ABSTRACT

Functionalizing pentacyclo[5.4.0.0^2,6.0^3,10.0^5,9]undecane-8-11-one and 1-phenyl-pentacyclo[5.4.0.0^2,6.0^3,10.0^5,9]undecane-8-11-one can be easily accomplished by using the alcohols of various alkynes and alkenes. Generally the synthesis of terminal alkyne and cyclic alkene ketal derivatives were performed fairly easily. Synthesis of the terminal alkenes provided some difficulties. Reduction of the alkyne ketal derivatives using Pd/CaCO\textsubscript{3} has been demonstrated to form a mixture containing the desired alkene ketal derivatives.

KEYWORDS

Cage compounds, diketone, ketal formation, reduction.

1. Introduction

The synthesis and chemistry of alicyclic compounds with cage structures has been the subject of research by many groups over the past 50 years. These cage structures have found applications in medicine where they, for instance enhance transport over membranes. A key step in the synthesis of such compounds are the photochemical cyclisation of a Diels-Alder adduct. The adduct of p-benzoquinone and cyclopentadiene has a structure with two double bonds within reach of each other in the same molecule, which undergoes photochemical addition to yield the highly strained dione \(^1\). In a similar manner the dione 2 can be synthesized by starting with 2-phenyl-1,4-benzoquinone. \(^4\)

In literature there are only a few examples exist of the synthesis of alkyne and alkene derivatives of 1.\(^5\) Functionalizing these diones with alkynes and alkenes provides many new possible substrates for inter alia alkynyl and alkene metathesis reactions as well as monomers for polymerisation reactions. In this paper we report the synthesis of alkyl ketal derivatives of different chain lengths as well as linear alkene and cyclic alkene ketal derivatives. Reduction of the alkyl ketal derivatives with Pd/CaCO\textsubscript{3} has been done to form a mixture containing the desired alkene ketal derivatives.

2. Results and Discussion

We found that the dione 1 gives various alkynes (3 and 4) and alkene 5 as well as the cyclic alkene 6 when reacted with various alkyne and alkene alcohols respectively in the presence of a catalytic amount of acid. When the dione 2 was used as the starting material instead of 1 similar results could be achieved (7 and 8). The yields for all the reactions are listed in Table 1. During our investigation we found that the terminal alkyne and cyclic alkene syntheses produced the easily isolatable crystalline products 3, 4, 6, 7 and 8. The alkene 5, which contains terminal alkenes, is obtained as light yellow oil. During the synthesis of 5 we found that a high yield could be achieved in one hour, but unwanted by-products formed in low yields, which could only be separated with tedious column chromatography separations. If the reaction was refluxed overnight no 5 could be isolated. We were unable to separate the by-products sufficiently for NMR analyses. Analysis by GC/MS indicated three major by-products that could not be identified unambiguously. In the other syntheses these by-products were not identified.

After several months the isolated compound 5 remained stable; no decomposition products were observed. This indicates that the by-product formation is dependent on the reaction conditions used during synthesis.

Although it is not indicated in the various schemes in this paper, all the products were racemic mixtures of equal distribution. The only exceptions were 7 and 8 where the main products were those indicated in the schemes. The ketal groups of the phenyl group are on opposite sides of the cage compound. The ratios of the racemic mixtures determined via GC-MS analysis were 9:1 for 7 and for 8 it was 30:1.

Recently Kotha et al.\(^9\) reported the ring-closing metathesis (RCM) of 9 with various Grubbs-type precatalysts in toluene to yield 10 in a high yield of 87 %.

In order to synthesize reagents for similar alkene metathesis reactions we performed alkyne to alkene reductions with Lindlar’s \(^11\) catalyst, Pd/CaCO\textsubscript{3}, in a hydrogen atmosphere.

on 3 and 4. In both cases a mixture of products were isolated in moderate yields as light yellow oils. GC-MS analyses of the oils showed a single broad peak for compounds 11 and 12, the ratio for this mixture to 13 were 76:23 and the ratio for 14, 15, and 16 were 35:35:30.

Complete conversion of the alkyne derivatives 3 and 4 were obtained as no alkyne CH- or C≡C-stretch absorption bands were observed in the IR-spectra of the resulting mixtures. Furthermore no molecular masses for 3 and 4, or the mono-alkyne derivatives 17 and 18 were observed using GC-MS after isolation. We were not able to separate compounds 11 to 16 from their respective mixtures. The complete reduction of 3 to 13 with 10 % Pd/C in a hydrogen atmosphere was performed to give an isolated yield of 93 %. Using the NMR data from 13 we were able to assign the NMR spectra of the mixtures of 11, 12, and 13, and 14, 15 and 16, respectively.

During the reduction of 3 with Lindlar’s catalyst the product formation was as follows: 3 → 19 → 11 → 12 → 13. The reduction of 4 followed the route: 4 → 20 → 14 → 15 → 16. If the formation of 17 or 18 takes place during the reduction, it is in such a small quantity that we were unable to isolate it. Although we chose a side at random in the schemes to illustrate the reduction process, we were not able to determine if reduction will take place first on the endo or on the exo branch of the ketal substituents.

3. Conclusions

The various synthesis methods discussed provide an easy and efficient way to synthesize various alkyne, alkene and cyclic alkene moieties of the diones 1 and 2 that can potentially be used as monomers for polymerisation and metathesis reactions.

4. Experimental

General methods

All reactants and solvents were used as received from the suppliers (Fluka, Adrich and Merck). All the diene- and diyne alcohols were distilled before being used. Infrared spectra (KBr-disk) were recorded on a Nicolet 550 Magna IR spectrometer and on a Bruker Alpha P ATR. EI spectra were obtained at 70 eV on a Micromass Autospec-Tof- and a Thermo DFS magnetic sector mass spectrometer (HRMS-EI). Reactions were monitored with an Agilent 6890 gas chromatograph equipped with an Agilent 7683 autosampler, HP-5 capillary column and an Agilent 5973 mass selective detector (MSD). 300 MHz 1H NMR and 75 MHz 13C NMR spectra were recorded on a Varian Gemini-300 spectrometer and 600 MHz 1H NMR and 150 MHz 13C NMR spectra were recorded on a Bruker Avance III UltraShield Plus 600 MHz spectrometer. All melting points were determined with a Buchi B-540 apparatus.
General procedure for the synthesis of alkene and alkyne ketals

In a Dean-Stark apparatus the dione, the alcohol and a catalytic amount of toluene-4-sulphonic acid was dissolved in benzene. The reaction mixture was refluxed for 1 to 24 hours. In some cases more alcohol was added to ensure the complete conversion of the substrate to product. The water that distilled off, very fast initially, was removed to help ensure that the product formation was maximized. The reaction was quenched by adding a 10% sodium carbonate solution to neutralize the acid. Extraction was done with 3 × 10 mL dichloromethane. The combined organic layers were washed once with water, dried over magnesium sulfate and filtered.

Pentacyclo[5.4.0.0²,6.0³,10.0⁵,9]undecane-8,8-diprop-2-ynyloxy-11-one (3): 1 (10.03 g, 57.6 mmol), propargyl alcohol (6.74 g, 120.2 mmol) and toluene-4-sulphonic acid (0.41 g, 2.4 mmol) were dissolved in 100 mL benzene and refluxed for 3 hours where after propargyl alcohol was added (5 mL, 85.9 mmol). After another 3 hours another portion propargyl alcohol was added (15 mL, 257.7 mmol) and the reaction was refluxed for 16 hours where after the reaction was stopped and isolated as described above. A pure product of 3 was obtained by recrystallization from absolute ethanol (12.84 g, 83 %, mp 122 °C) as an off-white powder.

General procedure for the Lindlar reduction of the alkyne ketal

In a round-bottom flask maintained under a hydrogen atmosphere Lindlar’s catalyst (10 % Pd/ CaCO₃), quinoline and the alkyne ketal were dissolved in acetonitrile. The reaction mixture was kept under hydrogen until a satisfactory conversion to the alkeno-ketal was achieved. The product was purified by performing flash chromatography (1:1 petroleum ether (60–80 °C):ethanol acetate).
ing the necessary funding and laboratory facilities to complete this work. We would also like to thank Mr. André Joubert for his valuable help in recording the NMR spectra.
