Date

7 November 2014

Ms A. Kotzé

Student number: 23288515
Declaration by supervisors

We hereby declare that this dissertation in article format was prepared under our supervision and we confirm that it meets all academic criteria for the process of awarding the academic degree. The candidate opted to write an article with the support of her supervisor and co-supervisor. We, the supervisors, declare that the input and effort of Alexa Kotzé in writing this article reflects research done by her. We hereby grant permission that she may submit this article for examination purposes in fulfilment of the requirements for the degree Magister Artium in Psychology.

Dr S. Jacobs

Dr. I. van Schalkwyk

5 November 2014
Declaration by editor

Confirmation of editing

I, Anne Kruger, professional, qualified and practising editor, hereby confirm that the Research Report and article of Alexa Kotze, titled The experience of early motherhood amongst Swazi Adolescent girls was edited by me in preparation for submission in November 2014.

Should you have any queries, kindly contact me on my cell phone no: 072 374 6272.

With thanks

Acknowledgements

I wish to express my sincere gratitude and appreciation to the following people:

My friend, counselor and Heavenly Father for giving me the opportunity to take part in this journey. Without His constant guidance, strength and new mercies every morning, I would never have been able to complete this challenge. Praise be to Jesus Christ!

My loving, super-hero husband, Johann Kotzé who daily encouraged me to persevere, who supported me through all the long hours and helped me to translate the siSwati interviews. Your passion for life and research helped me to see the importance of my research.

Dr Susanne Jacobs and Dr Izanette van Schalkwyk for assisting me in this research process, guiding me and encouraging me.

Desre Bates and Thobile Ngwenya who helped me with transcribing the interviews.

Jacky Pretorius, who assisted me with independent data analysis.

All my family and friends who supported me, whether it was by praying for me, phoning me, blessing me with food on the days when time was limited or understanding if I had to work when you came and visited us on the farm. A special thanks to my parents Dirk and Linda Visagie and parents-in-law Gert and Annetjie Kotzé who were always willing to babysit when I had to work and who encouraged me to persevere.

Our baby boy Ludwig Leo who “forced” me to finish this degree and helped me gain a new perspective on life and the experience of motherhood.

To all the adolescent mothers who were brave enough to make their voices heard and were willing to participate in this study.
Preface

This dissertation is presented in article format in accordance with the guidelines set out in the Manual for Postgraduate Studies 2013 of the North-West University and in conjunction with the guidelines of the Journal of Psychology in Africa. Guidelines for the submission to this journal are attached as appendix A.

The researcher used the APA 6 referencing method and the APA 6 guidelines for technical editing throughout the study. According to APA guidelines, Times New Roman, 12 font was used. Double line spacing and two spaces after punctuation marks, that end sentences, were adhered to.
Summary

Adolescent motherhood is a reality amongst South African adolescent girls from all cultures. However, there is a scarcity of information available on Swazi adolescents’ experiences of early motherhood. The research consequently aimed at exploring and describing the experiences of early motherhood amongst Swazi adolescent girls. The participants were encouraged to describe their unique lived experiences as to the early period of adolescent motherhood (pregnancy included). Positive psychology provided the theoretical framework, and phenomenology was used as the methodical design for this qualitative study.

Purposeful and snowball sampling was used to find the nine participants. Semi-structured one-on-one interviews were conducted with Swazi girls ranging from the ages of 16 to 20 years. The interviews were conducted in English as a second language of the participants, and they all resided within the Nkomazi municipality in Mpumalanga, South Africa. The collected data were analyzed according to the interpretative phenomenological approach (IPA) and five main themes were identified: (a) The influence of emotions; (b) Social support during early adolescent motherhood; (c) Challenges experienced during early motherhood; (d) Personal growth; and (e) Resilience.

The research findings indicate that early motherhood amongst Swazi adolescents comprises both positive and negative experiences and results in good and bad emotional experiences. All the participants experienced incidences in which their immediate environment (family, friends, community, neighbours, school, and boyfriends) rejected them and were unsupportive. This was especially evident in the ongoing lack of support offered by the biological father of the baby and the deterioration of original friendships.
Ultimately however, it became apparent that the inherent Swazi culture and African principle of “Ubuntu” resulted in their being mostly accepted and supported.

Furthermore, most participants experienced personal growth and a sense of maturity. Insights gained from motherhood resulted in participants making more responsible choices with regards to sexual behaviour, changes in their priorities, developing their characters, becoming more ambitious to achieve their personal life goals and becoming future orientated. The personal growth of most participants was clearly indicated by the mastering of several challenges related to early motherhood. A change in lifestyle was the most significant problem to overcome, and other challenges included the “burden” of being a provider, financial constraints in the present and future, interrupted education, loss of leisure time, and the experience of helplessness in times of need, for example when the baby is ill.

Despite the fact that adolescent motherhood was experienced as a difficult occurrence, most participants (six of the nine) demonstrated high levels of resilience. These participants demonstrated effective coping strategies by taking responsibility and ownership of the difficulties associated with adolescent motherhood, and expressed the desire to be good mothers.

Recommendations are given to enhance the well-being of Swazi adolescent mothers and the findings offer guidelines for a pregnancy prevention program as well as giving ideas on how to support adolescent girls in their journey of motherhood.

**Key words:** Swazi adolescents, motherhood, phenomenology, positive psychology, adolescent pregnancies
Opsomming

Adolessente moederskap is ‘n werklikheid wat voorkom onder Suid-Afrikaanse adolessente meisies van alle kulture. Daar is egter ’n tekort aan beskikbare inligting wat handel oor Swazi-adolessente se belewenis van vroeë moederskap. Die doel van hierdie navorsing was gevolglik om die ervarings van adolessente Swazi-moeders te verken en te beskryf. Die deelnemers is aangemoedig om hulle unieke geleefde en bewustelike belewenis van vroeë adolessente moederskap (swangerskap ingesluit) te beskryf. Positiewe sielkunde is gebruik as die teoretiese raamwerk en ’n fenomenologiese benadering is toegepas as die metodologiese struktuur vir hierdie kwalitatiewe studie.

Doelbewuste en sneeubal-steekproefneming is gebruik om nege deelnemers te kies. Semi-gestruktureerde, individuele onderhoude is met Swazi-meisies tussen die ouderdomme van 16 en 20 jaar uitgevoer. Die onderhoude is in die deelnemers se tweedetaal, naamlik Engels, gedoen en al die deelnemers was woonagtig in die Nkomazi munisipaliteit in Mpumalanga, Suid-Afrika.

Die ingesamelde data is volgens die interpretatiewe fenomenologiese benadering (IPA) ontleed en vyf hooftemas is geïdentifiseer: (a) Die invloed van emosies; (b) Sosiale ondersteuning tydens adolessentemoederskap; (c) Uitdagings ondervind tydens vroeë stadia van moederskap; (d) Persoonlike groei; en (e) Veerkragtigheid.

Die navorsingsbevindings dui daarop dat adolessente moeders onder die Swazi’s uit beide positiewe en negatiewe ervarings bestaan en goeie en slegte emosionele belewenisse behels. Al die deelnemers het beleef dat hul direkte omgewing (familie, vriende, gemeenskap, bure, skool en kêrels) hul verwerp het, of hulle nie ondersteun het nie. Dit het veral voorgekom in die deurlopende tekort aan ondersteuning van die biologiese pa van die kind en die geleidelike beëindiging van oorspronklike vriendskappe. Dit het egter duidelik geword
dat, in geheel, die inherente Swazi-kultuur en Afrika-beginsel van “Ubuntu” daartoe gelei het dat die adolessente moeders meestal aanvaar en ondersteun is.

Verder het die meeste deelnemers persoonlike groei en ’n mate van volwassenheid beleef. Die insigte wat met ma-wees opgedoen is, het daartoe gelei dat deelnemers meer verantwoordelike keuse maak ten opsigte van seksuele gedrag, veranderinge in prioriteite, karakterontwikkeling, meer ambisie om persoonlike doelwitte te bereik en meer toekomsgerigtheid. Die persoonlike groei van deelnemers was duidelik in die manier hoe hul uitdagings tydens die vroeë stadium van moederskap hanteer het. ’n Verandering in lewenstyl was die mees betekenisvolle probleem om te oorkom en ander uitdagings het ingeluit die “las” van versorger, finansiële beperkings in die hede en toekoms, onderbroke skoolonderrig, verlies van vrye-tyd, en die ervaring van hulpeloosheid in tye van nood, soos byvoorbeeld as die baba sick is.

Ten spyte daarvan dat adolessent-moederskap ’n moeilike belewenis is, het die meeste deelnemers (ses van die nege) hoë vlakke van veerkragtigheid beleef. Hierdie deelnemers het effektiewe hanteringsvaardighede gedemonstreer deur verantwoordelikheid en eienaarskap te neem van die uitdagings wat met vroeë adolessente moederskap geassosieer word. Hul het ook hul begeerte om goeie moeders te wees, verwoord.

Aanbevelings is gemaak om die welstand van adolessente Swazi-moeders te verbeter. Die bevindings verskaf riglyne vir ’n swangerskap-voorkomingsprogram (onder adolessente) sowel as idees oor hoe om adolessente moeders te ondersteun.

Orientation to the research

―When a girl becomes pregnant, her present and future changes radically, and rarely for the better. Her education may end, her job prospects evaporate, and her vulnerabilities to poverty, exclusion and dependency multiply‖ (United Nations Population Fund [UNFPA], 2013a, p. ii). Although there are many challenges associated with early motherhood, it is not necessarily all doom and gloom for adolescent mothers and their children. President Barack Obama, the 44th President of the United States of America and the first African-American to hold this office, is a child born from an adolescent mother. Ann Dunham—president Obama’s mother—fell pregnant at the age of eighteen years and the American president remarked that her strength was shown in many ways. President Obama’s mother managed to raise her children successfully, and achieved her dreams by completing her Doctorate in Anthropology. It is considered that she played a major role in teaching him values and shaping him into the man that he is today (Scott, 2012).

The focus of this study was to explore and describe the experience of early motherhood amongst Swazi adolescent girls in its entirety, not giving prevalence to just the negative experiences but also highlighting the positive experiences as to these girls’ lived realities. The first part of this chapter commences with the stating of the problem by providing a broad statistical overview of the predicament that the world and more specifically South Africa, is in with the current state of adolescent pregnancies. Literature is used to give an explanation about the types of difficulties adolescent mothers experience at their specific phase of development and the impact it has on their lives, as well as the possible experiences their children might have, being born in this specific environment. The theoretical framework underpinning this study, the rationale of the study and the research methodology is discussed and the chapter will end off with a summary and conclusion before giving an
integrated overview of other important literature focusing on the underlying theories and models suitable for the study of adolescent motherhood in part II.

**Problem statement**

Adolescent pregnancies and early motherhood are rife all around the world and it is a dilemma that exists across all cultures in both developed and developing countries (UNFPA, 2013a). It is estimated that worldwide annually 13.1 million girls between the ages of 15 to 19 years give birth, with 95% of these births occurring in developing countries with a low or middle income (UNFPA, 2013a). Amongst the developed countries, the United States of America has the highest tendency towards adolescent pregnancies with 329,772 births being recorded in the year 2011 (UNFPA, 2013a). As for the developing world, almost one in five women fall pregnant before they turn 18, and up to one in four in East and Southern Africa (UNFPA, 2013b). Poorly educated, impoverished and rural adolescent girls have a higher risk of becoming pregnant than wealthier urban girls (UNFPA, 2013a). This is evident when looking at some of South Africa’s neighbouring countries, Swaziland, Zimbabwe and Mozambique, which present statistics indicating that twenty percent or more of women aged 20-24, gave birth before the age of 18 years (UNFPA, 2013a). Since South Africa is part of the statistics regarding developing countries, it means that South Africa is one of the countries where the largest percentage of adolescent pregnancies occurs.

In South Africa, African adolescents have the highest rate of adolescent pregnancies (13 percent), contrasting with Whites and Indians both at two percent and Coloured adolescents at ten percent (Department of Health, Medical Research Council, OrcMacro, 2007). This implies that adolescent pregnancies are a reality in South Africa across all cultures and that this matter should be taken seriously.

According to the South African demographic and health survey of 2003 (Department of Health, Medical Research Council, OrcMacro 2007), 12% of South African women
between 15–19 years are mothers or are pregnant with their first child. The latest statistics show that approximately 4.5% of all South African adolescents aged 13–19 reported to be pregnant during the year preceding the General Household Survey in South Africa 2009–2011 (Statistics South Africa, 2012b). It is important to emphasize that in the latter survey, the number of already existing adolescent mothers was not accounted for and therefore the researcher argues that a realistic indication of the phenomenon was not given. In the same year that the General Household Survey commenced, research indicated that although fertility rates in South Africa are declining, adolescent pregnancies are declining at a slower pace than overall fertility (Maholo, Maja, & Wright, 2009; Panday, Makiwane, Ranchod, & Letsoalo, 2009), implying that adolescent pregnancies and early motherhood in South Africa remain a predicament.

In order to capture the full extent and impact of being an adolescent mother, the researcher is of opinion that a basic understanding of what adolescence and motherhood as separate entities entail, should be understood. These concepts, namely motherhood and adolescence will be discussed in more detail in section A part II.

Adolescence as a life phase

Adolescence as the transition phase between childhood and adulthood is characterized as a stage entailing great psychological and physiological changes and challenges (Reber, Allen, & Reber, 2009). In short, this life phase is a particular confusing and uncertain time in a person’s life. Apart from several physical, social and emotional milestones, adolescence entails many developmental tasks, such as the development of identity and self-image, refining of morals and values, experimentation with risky behaviour, dealing with peer pressure, and making future-related choices (Collins, 2008; Macleod, 2003; United Nations Children's fund [UNICEF], 2011). Also, Sigelman and Rider (2011) underline the changes and challenges associated with physical growth and puberty in order to reach sexual maturity.
One of these physical changes involves the possibilities of being sexually active, being pregnant and becoming a mother (Collins, 2008; Macleod, 2003).

**Motherhood**

Becoming a mother is a life changing situation for any woman (Paris & Helson, 2002). Motherhood and pregnancy is associated with physical and psychological change, loss or adaptations and attachment for the mother (Burmeister, 2005; Gross & Pattison, 2007). According to Akujobi (2011, p. 2), motherhood elicits “a automatic set of feelings and behaviours that are switched on and triggered by pregnancy and the birth of a baby”. Behavioural changes could already occur in the first trimester and a shift of consideration from the self to the foetus occurs commonly (Darvill, Skirton, & Farrand, 2010). In addition, women’s accounts of motherhood show that the process of becoming a mother is rarely unproblematic, being characterized by disruption and ambivalence, as well as happiness and fulfilment (Miller, 2005; Shelton & Johnson, 2006). Besides the physical changes, some of the main psychological struggles in the mothering-process have been described in the following manner: Being drained, feeling alone and unsupported, unready, experiencing a sense of loss, and a process of trying to understand the meaning of motherhood (Barclay, Everitt, Rogan, Schmied, & Wyllie, 1997). It seems that despite common positive perceptions surrounding motherhood, it can be a very challenging experience, since it is seldom trouble-free. Taking into account the several physical, social and emotional changes and challenges that both adolescence and motherhood entail, it seems that being an adolescent mother could further complicate the situation.

**Motherhood and adolescence: Two different life realities**

Jomeen (2010) states that the experience of motherhood is difficult for modern women who do not have children in the right circumstances at the appropriate time. This statement can refer to young mothers who have to deal with challenges of adolescence and
being a mother simultaneously; two realities which seem to be in conflict with one another (Sadler & Cowlin, 2003). The adolescent girl is suddenly forced to rapidly go from one life phase to the other and shifting her energy and time away from her own developmental tasks to those of motherhood (Sadler & Cowlin, 2003). While the adolescent mother is still in the process of “finding herself”, figuring out who she is in the world and amongst her peers (Sigelman & Rider, 2011), her newly acquired maternal role hinders her developing identity (Sadler & Cowlin, 2003). Her role as mother compels her to care and plan for her baby instead of spending time with her peers (Sadler & Cowlin, 2003). The young mother's egocentric way of thinking, which is inherent in adolescence (Elkind & Bowen, 1979) is challenged when having a baby. An adolescent might not have developed the cognitive ability and reasoning that is required in order to plan for the child’s future, safety and various needs as is expected of a mother (Sadler & Cowlin, 2003). The adolescent’s desire to function independently becomes difficult as she often needs to rely on family members for financial and social support and guidance. Finally, adolescent mothers, although being sexually active, might still feel slightly uneasy with their developing bodies and sexuality (UNICEF, 2011), and must now all of a sudden cope with the bodily changes associated with pregnancy, breast feeding and the post-partum period (Sadler & Cowlin, 2003). In summary, adolescent motherhood poses numerous challenges that require adjustment and many compromises (Kaufman, De Wet, & Stadler, 2001).

**Difficulties associated with being an adolescent mother**

Being an adolescent mother can give rise to several social and psychological problems (Richter & Mlambo, 2005). Adolescent mothers have a higher risk for post-natal depression (Figueiredo, Bifulco, Pacheco, Costa, & Magarinho, 2006), which in turn could influence parenting skills (Reid & Meadows-Oliver, 2007) and result in a greater likelihood of poorer attachment styles with their children (Flaherty & Sadler, 2011). Some adolescent mothers
report on the negative influences their pregnancy and motherhood have on relationships with their families, friends and the fathers of the child (Rolfe, 2008; Spear, 2004).

Adding to these challenges are the incidences of fathers who reject the mothers and babies and choose to disappear with new girl-friends, refusing to take responsibility for their children and their role as a father and partner (Kaye, 2008; Lehana & Van Rhyn, 2003). This is of great concern, seeing that a good and satisfying relationship with the father of the child has proved to enhance the mother-child attachment and decrease maternal distress (Parekh & De la Rey, 1997). Some adolescent girls experience the loss of friendships due to their own preoccupation with their babies—their new responsibility—(Dlamini, Van der Merwe, & Ehlers, 2003) and others experience the disrespect and mocking attitudes of their peers during pregnancy (Mkhwanazi, 2010).

Although South Africa’s Constitution permits adolescent mothers to return to school after giving birth (Chohan, 2011), dropping out of school because of pregnancy and not returning to school after the birth of the baby still remains a predicament (Grant & Hallman, 2006). This can lead to limited future career options and lowering the adolescent’s socio-economic status (Grant & Hallman, 2006; Lehana & Van Rhyn, 2003; Macleod, 1999). Then again, in contrast with these findings, about a third of adolescent mothers (Panday et al., 2009) do return to school to complete their education (Chohan, 2011; Maholo et al., 2009), but seemingly not without encountering challenges (Kaufman et al., 2001). Girls who do return to school often find it hard to balance their school responsibilities and looking after their babies (Kaufman et al., 2001), especially if their babies are ill (Chohan, 2011).

Even though schools in South Africa are obliged to support young women who become mothers, it is unfortunately not always the case (Bhana, Morrell, Shefer, & Ngabaza, 2010). Bhana and Mcambi (2013) have shown that seven African girls from a KwaZulu-Natal school —consisting of low-income to middle class learners—experienced limited
support from their school and educators. The adolescent girls felt stigmatized during their pregnancies and were exposed to insensitive educators and peers. Panday et al. (2009) report similar findings and further mention that pregnant learners, namely girls, are sometimes expelled from school.

Adolescent mothers seldom have any income to support a child and have to rely on family members (Spear, 2004), and/or child support grants to provide in the financial needs of their children. However, research shows that between 1999 and 2005 fewer than three percent of recipients of the child support grant in South Africa have been adolescents, despite the fact that the total fertility rate in 2005 was as much as 15 percent (Makiwane, 2010). This highlights the financial stress that most South African adolescent mothers endure.

Despite the difficulties and hardships accompanying adolescent pregnancy, many adolescent mothers fail to commit to the postponement of a second child (Whitman, Borkowski, Keogh, & Weed, 2001) and have their second child within two years of their first child. These statistics are especially high for mothers in the US with 25% of them falling pregnant within two years of having their first baby. This can be ascribed to the fact that adolescent mothers develop a sense of independency and responsibility after raising their first child (Whitman et al., 2001). However, a recent South African study has indicated that the use of contraception amongst adolescent mothers has increased to such a point that increasingly adolescents postpone the birth of a second child to their mid-twenties (Panday et al., 2009). It is also proposed that educational opportunities for adolescent mothers are an incentive to delay a second birth (Kaufman et al., 2001). It seems overall that being an adolescent mother is linked to various difficulties and hardships. Besides the mother, these complications influence the lives of their babies and/or children.
The effect of adolescent motherhood on their children

Another aspect that must be considered is in what way adolescent motherhood affects the adolescent mothers as well as their babies. Adolescent pregnancy has been found to be intergenerational (Kirby, Laris, & Rolleri, 2007). In other words, it is often a negative cycle that repeats itself. Daughters of adolescent mothers are more likely to become adolescent mothers themselves, and sons of adolescent mothers are more likely to be imprisoned (Hoffman, 2006).

Research indicates that children of adolescent mothers are mostly unplanned (Finer & Zolna, 2011; Mkhwanazi, 2010; Whitman et al., 2001), often born prematurely (Panday et al., 2009) or have low birth weight (Hoffman, 2006) and are prone to developmental and intellectual delays (Whitman et al., 2001). They are also at risk for developing poor attachment styles (Belsky & Fearon, 2002). Attachment can be defined as “. . . an emotional bond formed between an infant and one or more adults”, usually the mother (Reber et al., 2009:69). The attachment styles of children are especially important since failure to form a good attachment with a parent can result in their sense of self being incomplete, fragmented and with a limited sense of autonomy. The implication is that their ability to handle difficult situations as well as the relation to others and the world around them both as children and as adults is influenced (Hughes, 1997). Adolescent motherhood disrupts normal adolescent development and the attainment of the appropriate emotional and cognitive capacities essential for maternal behaviours that foster secure attachment (Flaherty & Sadler, 2011). However, it seems that with appropriate interventions and support in developing attachment, children of adolescent mothers can obtain higher rates of secure attachment than normative samples in this population (Flaherty & Sadler, 2011).

Since many toddlers of adolescent mothers are exposed to enduring poverty, they are more likely not to attend pre-school and are often more exposed to dysfunctional parenting,
such as aggressive behaviour of their parents or care-givers (Whitman et al., 2001). Also, children of adolescent mothers are more prone to dropping out of school, have poorer academic performance and poorer school attendance (Kirby et al., 2007; Panday et al., 2009).

Macleod (2003) stresses that although adolescents are no longer children, neither are they adults, which implies that in general the adolescent mother cannot take care of her child independently as she herself still needs to be looked after (Flaherty & Sadler, 2011). Children of adolescent mothers are therefore often sent away to be raised by other family members, for example the grandmothers, to improve the life chances of the adolescent mother (Kaufman et al., 2001) or to allow the mother to return to school (Maholo et al., 2009). Kaufman et al. (2001) argue that although this is not necessarily a bad thing, little research has been done about the well-being and fate of the first-born child being raised by the extended family in South Africa. The afore-mentioned issues must be viewed from a 21st century perspective, and the role of culture and context should be considered.

Experiences of pregnancy and motherhood by girls from different cultures

Although the experiences of motherhood such as being pregnant, giving birth and nurturing children are universal and part of human existence, motherhood is a subjective and unique experience and is embedded in a woman's culture and context (Akujobi, 2011). The following section gives a bird's eye view of how adolescents from different cultures experienced pregnancy and motherhood.

From the literature it becomes clear that Sesotho adolescents in Maseru experienced the initial reality of pregnancy with a combination of disbelief, confusion and disappointment which suggested that they were far from being ready for the prospect of motherhood (Lehana & Van Rhyn, 2003). In the Sesotho culture it used to be a common traditional practice for the elders to give sexual education to the young people through initiation school or gatherings but a recent study suggested that the Sesotho adolescents felt that it was not as
popular anymore. These adolescents especially felt that their mothers failed to give them information about the "facts of life" (Lehana & Van Rhyn, 2003). The neglect by parents to discuss sexual matters like contraceptive use, and pregnancy with their children was also experienced by the English and Xhosa speaking girls in Nyanga township in Western Cape province. This neglect was recognized as one of the reasons why teenage pregnancy occurred amongst these girls (Mkhwanazi, 2010).

The majority of the Sesotho girls from Maseru interviewed by Lehana and Van Rhyn (2003) experienced their pregnancy in a negative way and felt that they had forfeited their experience of being an adolescent. English girls, from different ethnic groups in Britain, also voiced regrets by not applying principles of family planning and regretted not waiting longer before having a baby, therefore mourning the loss of childhood experiences (Rolfe, 2008).

The Sotho girls further felt robbed of their future educational possibilities and their opportunity for a good life with reference to the socio-economic aspects. They did however state that they didn’t perceive the pregnancy as the complete destruction of their future dreams. Many of them expressed the desire to complete their education, to find a job and to work hard in order to provide successfully for their children (Lehana & Van Rhyn, 2003).

The Sotho adolescent girls from Maseru experienced support from their mothers during their pregnancy, but then again, the lack of support from their friends was experienced as distressing. They pointed out the need for new friendship of girls in similar situations (Lehana & Van Rhyn, 2003). It was shown that these adolescents felt the need to verbalise their experiences and difficulties and elaborated on the rejection they had experienced from the baby’s father after falling pregnant (Lehana & Van Rhyn, 2003). Four of the five women from a rural area in South Africa, who became mothers during their adolescent years, also experienced the impact their motherhood had on the relationship with the father of their babies and that their social relationships in general were adversely affected (Sodi & Sodi,
Two of the girls indicated the difficulties they had had with their own fathers and the resentment experienced from them due to their pregnancies. Caution was also expressed over investing in new romantic relationships as this could lead to their babies feeling neglected or diminishing their need to feel independent (Sodi & Sodi, 2012).

For these Tshivenda, Xitsonga and Sepedi speaking girls in the above mentioned study, the experience of motherhood included several negative emotional problems. Feelings of self-blame, sadness, isolation and lack of interest were expressed and one of the participants had strong feelings of depression. For these girls, motherhood was unplanned and led to significant lifestyle changes (Sodi & Sodi, 2012).

Similarly, significant lifestyle changes have also been experienced by Zulu adolescent mothers from a semi-rural area in KwaZulu-Natal. Parekh and De la Rey (1997) reported that one of the greatest lifestyle changes included balancing the roles of being a scholar and a mother simultaneously and making sure that enough attention was given to both the baby and their school work. Just like in previous studies mentioned, these adolescent mothers also experienced varying support from their friends and not having enough time to visit friends resulted in lost friendships. Although they eventually experienced support from their families, their family relationships were not without difficulties. Several participants felt that they had to be exceptionally well-behaved in order to make up for the disappointment that they had caused their families and they were subjected to initial reactions of shock and anger from parents and caregivers. The fathers of the adolescent girls were once again, just as in the case of the Sotho girls from Maseru (Lehana & Van Rhyn, 2003), more reluctant to offer acceptance and their anger was more visible than that of the mothers of the adolescents. The mothers and grandmother were experienced as most supportive (Parekh & De la Rey, 1997). It is evident that although the experiences amongst the adolescent mothers differ in different cultures, there are also many similar experiences.
Positive experiences and outcomes of motherhood amongst adolescent girls

During the literature review it became apparent that there is often an overemphasis on and general assumption that adolescents experience motherhood as negative, resulting in mainly negative outcomes. Chohan (2011) proposes that adolescent motherhood does not necessarily only have negative outcomes. This South African study with eight adolescent girls from a public school in Johannesburg indicates that girls showed significant personal growth and maturity through the process of motherhood. It became evident that being an adolescent mother increased their sense of responsibility and encouraged them to persevere and to complete their education. Chohan (2011) indicates that the experience of positive emotions, such as happiness, excitement and a sense of fulfilment were an integral part of motherhood for these adolescents. It is interesting to note that a study done with young people in Brazil suggested that the adolescents regarded adolescent pregnancy as neither a social nor a health problem. Findings indicated that youngsters in Brazil described pregnancy and motherhood as assisting girls in developing a positive identity and equipping them with status and visibility in the community (De Carvalho, 2007).

Studies amongst other cultural groups have also indicated that some adolescents have positive experiences in becoming mothers (Furstenberg, Brooks-Gunn, & Morgan, 1990). For example, the account of unmarried adolescent girls in Maseru reported acceptance and support from families, boyfriend/sexual partner, friends and community members during their pregnancies (Lehana & Van Rhyn, 2003). Macleod (2003) emphasizes how teenagers may see becoming a mother as a pathway to the desired status of adulthood. There is an assumption that where gaining adulthood through marriage is delayed, the girl may attain adulthood status through bearing a child.
Furthermore, adolescent girls from Swaziland are of the opinion that starting childbearing whilst still being a teenager (18 years of age) is ideal and would enable a woman to bear the optimum number of children in her lifetime (Ziyane & Ehlers, 2006).

Central research question

What are the experiences of early motherhood amongst Swazi adolescent girls?

Rationale of the study

Lack of research with regards to the experience of motherhood specifically

The myriad of difficulties associated with adolescent motherhood are considered important background information for promoting further studies with regards to: i) adolescents' experiences of motherhood; ii) how early motherhood impacts their lives; and iii) how adolescent mothers can be supported. However, the existing research globally and in South Africa on adolescent pregnancies has focused more on the perceptions on the use of contraceptives, HIV and risky sexual behaviour. Limited research is available with regards to adolescent motherhood per se. Shaw and Lawlor (2007) who performed a Medline search between January 2000–September 2003, discovered 256 qualitative research articles, reviews or papers on any aspect of adolescent pregnancy. Amongst the 256 research papers only 4% were aimed at supporting adolescent mothers, indicating support focused primarily on the antenatal or immediate post-natal period. Forty percent of the articles were aimed at analysing adolescent pregnancy prevention strategies and 26% of the studies focused on the potential health and social problems associated with adolescent pregnancy. Research addressing the varied South African circumstances in relation to the experience of motherhood is largely absent from the literature (Kruger, 2005) and therefore this study will contribute to this gap in research.
Lack of research amongst Swazi adolescents in South Africa

Besides limited research on adolescent motherhood in South Africa, there remains a void in the literature regarding adolescent Swazi girls’ experience of motherhood, and research amongst the Swazi cultural group in general. In South Africa, 129 7046 people are siSwati speaking of which 110 6588 siSwati people reside in Mpumalanga (Statistics South Africa, 2012a). The Swazi people in South Africa have strong family, cultural, traditional and economic ties with Swaziland, thereby increasing the probability that studies from Swaziland would have similar findings in the area of study. In Swaziland, 28% of girls became pregnant before their eighteenth birthday for the time period 2000 to 2009 (UNICEF, 2011). Compared to the world average of 15% (calculated in the same study), Swazi girls seem to be especially prone to adolescent pregnancies making this cultural group particularly valuable for research purposes.

Necessity of doing a phenomenological study

Youngleson (2007) proposes that there is a need to focus on the emotions and feelings that mothers experience concerning motherhood. By engaging with the adolescents themselves, first-hand information could be gathered on the experiences of how adolescent girls from a Swazi culture experience early motherhood, instead of relying on assumptions and perceptions from girls of other cultures e.g. the Vendas from Lesotho (Lehana & Van Rhyn, 2003) or Coloureds from Kylemore community in the Western Cape (Youngleson, 2007). The phenomenological approach therefore allowed the researcher to focus on the ‘how’ of the adolescent Swazi girls’ personal experiences, feelings and convictions on motherhood in the present moment rather than trying to interpret the reasoning or the ‘why’ behind the lived phenomena (Joyce & Sills, 2009).
Significance of adolescent-specific research

Adolescent participation in discussions related to development, health and security has become more prevalent in the literature. Internationally, adolescents are now given the opportunity to make their voices heard by participating in conventions, forums and strategic planning such as the State of the World's Children report (UNICEF, 2011). In view of the above-mentioned it is important to recognize the valuable descriptions and knowledge that can be obtained by interviewing adolescents. Afable-Munsuz, Speizer, Magnus, and Kendall (2006) verify this by outlining that a phenomenological study on the personal experience of adolescent motherhood can be important to inform other adolescents more effectively on the topic of adolescent pregnancy and motherhood.

In summary, the problem that exists is that there are many incidences of adolescent Swazi mothers in South Africa and little is known about their personal, subjective experience of this occurrence in their lives.

Theoretical framework

Positive psychology comprises the scientific study of optimal human functioning. This approach does not deny problems or difficulties that people might experience (Peterson, 2009), but it embraces two dimensions, namely, well-being as well as pathology. It must be stated that for this research the well-being dimension was chosen. The perspective of positive psychology is a suitable theoretical framework for this study, seeing that the participants of the study were not suffering from disease or disorder, and could be viewed as belonging to the non-clinical population of South Africa.

Health is described as a state of complete physical, mental and social well-being and not merely the absence of disease (World Health Organization, 1948). Well-being is a complex construct that concerns “optimal experience and functioning” (Ryan & Deci, 2001:141), namely the eudaimonic component of well-being, as well as the hedonic
component which embraces the subjective dimensions of wellness such as emotions and feelings. For purposes of this research, high levels of psychosocial well-being are conceptualized in terms of flourishing as described by Keyes (2007). Keyes (2003, 2007) defines flourishing as a state in which an individual feels positive emotions toward life, and is functioning well psychologically as well as socially. He links the concept of flourishing or high well-being to approaches aimed at enabling people towards positive human health.

Van Schalkwyk and Wissing (2013) emphasized that the mere absence of ill-being does not mechanically imply well-being, just as the mere absence of an illness, such as pneumonia, does not indicate high levels of physical fitness. Not all people who are free of a mental illness feel healthy or function well in everyday life (Keyes, 2005). Keyes (2003) refers to the absence of mental health, without the diagnosis of a mental illness, as languishing. He further explains this by saying that languishing refers to a person who is not functioning well psychologically or socially, but s/he is not suffering from depression, but rather is lacking positive emotions towards life (Keyes, 2003). Languishing can therefore be regarded as the indication of low levels of well-being. An individual who is moderately mentally healthy is neither flourishing nor languishing in life (Keyes, 2005). Then again, flourishing is indicated by healthy relations; positive emotions; resilience; superior health; and, optimal functioning. One of the leading researchers in the area of positive psychology, Martin Seligman, has indicated that although positive psychology originally focused on authentic happiness, he is now of opinion that the topic of positive psychology is that of well-being and the measuring of the degree to which a person is flourishing (Seligman, 2011).

Van Schalkwyk and Wissing (2010) indicated that South African adolescents experience flourishing as purposeful living; experiencing positive relationships with primary caretakers, friends and God; having role-models to guide them and being a role-model to others; having self-confidence and positive self-regard; partaking in a constructive lifestyle;
are constructively coping; are experiencing positive emotions and are having a positive approach on a daily basis. Languishing was understood and experienced by the adolescents as having a meaningless life; impaired relationships with family, friends and God; identifying and associating themselves with dysfunctional people; having low self-confidence; partaking in destructive behaviours for e.g. substance abuse or criminal behaviour; not acknowledging emotions or having negative emotions; and continuously experiencing a sense of hopelessness. It was found that approximately 60% of the adolescents that participated in the study were not flourishing (i.e. functioning at optimal level of mental health) indicating the dire need for facilitating well-being in adolescents in order to ensure flourishing (Van Schalkwyk & Wissing, 2010).

Although positive psychology provides a scientific perspective to examine well-being, it does not imply a polyanna approach (Diener, 2009), but it can be seen as the lens to fortify when dealing with life challenges. In this sense it is of crucial importance to state that resilience is linked to high well-being, namely flourishing (Keyes, 2002) since resilience is seen as a building block of well-being and rooted in positive psychology (Koen, Van Eeden, Wissing, & Koen, 2013). Resilience signifies patterns and processes of positive adaptation in the midst of significant risk (Masten & Wright, 2010; Obrist, Pfeiffer, & Henley, 2010). A focus on resilience does not imply the treatment of disorders but rather the enhancement of the well-being of individuals, families and communities under stress and emphasizing the observable mechanisms and processes they use to cope, adapt and overcome adversity (Ungar, 2012). This means that resilience is about the experience of and effective dealing with contextual difficulties and personal challenges.

The definition of resilience centres around two conditions: firstly, the individual has been subjected to risk or adversity; and second, the individual managed to achieve a positive outcome despite the adversity and has returned to original level of functioning or is
functioning at a higher level of well-being (Masten, 2001). Resilience can manifest as different processes depending on the culture and context and therefore resilience is best understood if culture and context is kept in mind (Ungar, 2012; Van Schalkwyk & Wissing, 2013). Also, apart from personal protective or risk factors (Masten 2001), resilience entails the interacting of individuals and their environment in such a way that the individual benefits psychosocially. This interaction can be described as a dynamic process influenced by internal factors and environmental factors that lead to positive outcomes (Richardson, 2002; Tugade & Fredrickson, 2004). In order for resilience to occur, a person must take action to engage support and the environment in which the person is rooted must actively offer support (Masten & Wright, 2010; Theron, 2013). In other words, resilience is both dependent on an individual’s personal traits and characteristics for example, having a strong sense of self-worth, having empathy, autonomy, problem solving skills and the capacity to self-regulate (Gunnestad, 2006; Masten & Wright, 2010) as well as being exposed to wellness-promoting resources in the individual’s socio-cultural milieu for example, having positive attachments to significant others and having existential support in the form of cultural traditions, spirituality, values and belief systems (Masten & Wright, 2010). Many researchers have identified protective factors that can create resilience by building a positive self-image, reducing the effect of risk factors, breaking a negative cycle and creating new opportunities for an individual (Rutter, 1990).

Protective factors can be defined as factors within the individual and in the individual’s environment, and the interaction between these factors that give a person the strength, skill and motivation to cope with adversities and to re-establish normal life (Gunnestad, 2006). The challenge model of resiliency suggests that a stressor / risk factor can be treated as a potential enhancer of positive adaptation provided that the challenge is not too difficult.
If the individual is successful at overcoming the challenge it will strengthen the person but if unsuccessful, the individual may become vulnerable to risk (O’Leary, 1998). Research on resilience further suggests that the presence of positive emotions are important tools for ensuring well-being and enhancing coping and resilience (Folkman & Moskowitz, 2000; Fredrickson, 2013).

Hall and Torres (2002) emphasize the need for researchers to focus on adolescent well-being. Previous research has identified the need for a balanced perspective on adolescents by focusing both on the risk factors that increase vulnerability amongst adolescents and the protective factors that allow them to adapt despite adversities; in other words to be resilient (Van den Berg et al., 2013). It is important to note that previous research have found that the well-being of adolescents and their ability to be resilient is closely related to the social support they receive; the ability to experience a sense of mastery; experiencing a sense of relatedness; school functioning; emotional regulation and emotional reactivity (Van den Berg et al., 2013).

**Aim of the research**

The aim of the study was to explore and describe the experience of early motherhood amongst Swazi adolescent girls.

**Central theoretical statement**

By exploring and describing the lived experiences of early motherhood amongst Swazi adolescent girls in the Nkomazi area of Mpumalanga province, first-hand information from the adolescents themselves can be obtained in order to gain an understanding of their experience of early motherhood. This information can be used in future to provide guidelines for an educational pregnancy prevention programme in South Africa by increasing awareness of the challenges associated with motherhood, the impact it has on the lives of adolescent girls and the importance of responsible motherhood. Furthermore the information can also
provide guidelines for establishing a support programme that will equip the girls for the task of early motherhood.

The next section will cover some important definitions of this research, namely, adolescence; motherhood and early motherhood; motherhood and the role of culture.

**Definitions of concepts**

**Adolescence**

**Defining adolescence.**

In order to understand the full extent of the experiences, consequences and significance regarding adolescent pregnancies and adolescent motherhood, it is necessary to recognise certain information and "truths" versus myths concerning the definition and nature of adolescent development and adolescent sexuality.

Adolescence can be defined as "the period of development marked at the beginning by the onset of puberty and at the end by the attainment of physiological and psychological maturity" (Reber et al., 2009:15). According to Kaplan and Sadock's Synopsis of Psychiatry (Saddock & Saddock, 2003), adolescence is frequently divided into three periods: Early (ages 11–14), middle (ages 14–17), and late (ages 17–20). However, authors, psychologists and organizations differ in opinion of what ages can be attached to the term "adolescence". Both the United Nations Population Fund (UNFPA) and the World Health Organization (WHO) classify adolescence between the ages of 10 and 19 in contrast with the World Programme of Action for Youth and the International Labour Organisation (ILO) who describe adolescence as between the ages of 15 and 24 (Department of Economic and Social Affairs [DESA], 2007; UNICEF, 2011). Children reach puberty at different ages and their physical, mental, sexual and psychological growth occurs along a continuum that differs from individual to individual (Saddock & Saddock, 2003; UNICEF, 2011), therefore it is hard to assign a specific age category to the term adolescence and it should rather be seen as a transitional
phase between childhood and adulthood (DESA, 2007). Donald and Dawes (1994) argue that in countries such as South Africa that has a mixture of different races, classes and cultures, there are both commonality and discrepancies in the way childhood [and adolescence] is construed, implying that the meaning of childhood and adolescence differs in various contexts. Macleod (2003) affirms this by stating that the education system with extended schooling in South Africa lends itself to extending the age of adolescent participants to 21 years of age. It was thus decided to include adolescent girls from the ages of 12 to 21 years in the inclusion criteria for this study in order to cover the whole spectrum of adolescenthood.

In short, adolescence can be described as the phase in which the body changes and prepares for sexual maturity with increased production of gonad hormones. Girls typically show physical signs of puberty earlier than boys with menarche, the first menstruation, being the most dramatic event in their sexual maturity (Sigelman & Rider, 2011). The adolescent developmental phase constitutes a period of great change, challenges and development particularly in a girl’s life and should not be taken for granted when doing research with this particular age group.

**Motherhood**

**Early motherhood.**

Adaptation to motherhood is a transition that commences prior to pregnancy with the decision-making process of when to have a child (Benzies et al., 2006) and continues throughout the early weeks and months after the birth of the baby (Tulman & Fawcett, 2003). The post-partum period is characterized by the new mother’s adaption in the form of role acquisition, learning how to nurture her infant and bonding with her child (Mercer, 1995) whilst still fulfilling existing roles, for example, employee, friend, wife (O’Hara, Hoffman, Philipps, & Wright, 1992). The period between three weeks post-partum up to four to six
months post-partum is characterized by the integration of new feelings and experiences relating to identity, relationships and functioning, leading to the adoption of a new identity as a mother (Mercer, 1995; Tulman & Fawcett, 2003). Although each woman’s experience of becoming a mother is unique, most women find adaptation to motherhood challenging yet positive (Aber, Weiss, & Fawcett, 2013). The biggest disruption of a woman’s lifestyle takes place in the early post-partum period when adjustment to a new reality needs to be made. Yet motherhood is a lifelong commitment. Challenges such as loss of personal time and space and infant care demands are ongoing (Aber et al., 2013) and high levels of post-partum fatigue can persist well into the second year after childbirth (Parks, Lenz, Milligan, & Han, 1999). Mercer (2004) describes becoming a mother as a dynamic and evolving process as opposed to a state that is attained. It is evident that with every new challenge associated with child rearing, the mother needs to adapt and normalise the occurrence in her day-to-day reality. The demanding nature of this process can be stressful (Beck, 1996) and exceed the mother’s expectations of motherhood (Logsdon, Wisner, & Pinto-Foltz, 2006), but generally a mother’s overwhelming love for her baby motivates her to persevere despite these stressors (Weaver & Ussher, 1997).

**Motherhood: The role of culture and context.**

It is important to highlight that the experience of motherhood differs from woman to woman and the issue of social context and culture should be taken into account (Akujobi, 2011). It also differs with regards to what is considered socially appropriate practices of childbirth and child rearing (Hays, 1996), causing the concept of motherhood to be invested with ideological meaning that is culturally specific (Parker, 1997). While adaptation to motherhood has many normative aspects across generations and cultures (Aber et al., 2013), the woman’s cultural beliefs, religion, socio-economic status and social norms strongly influence her transition to motherhood (Meleis, Sawyer, Im, Hilfinger Messias, &
Schumacher, 2000). In other words, in order to fully understand a woman’s experience of motherhood, her specific culture should be kept in mind. Many religions and cultures all over the world assign a very important status to motherhood in a women’s life. In Africa, motherhood is seen as a gift from God and a sacred role that women need to play and is associated with characteristics such as nurturer, provider and goddess (Akujobi, 2011). The centrality of motherhood in African society is emphasized by the act of self-sacrifice and regardless of the women’s desires, talents and dreams, her primary function is that of motherhood (Akujobi, 2011).

Cultural expectations, as indicated have ignited many feministic movements and research to proclaim that although motherhood is vital, women should be given a choice whether they want to experience motherhood or not (Akujobi, 2011). The social concept of the experience of motherhood can be misleading and may lead to disillusionment and depression for the new mother (Weaver & Ussher, 1997). Feminists encourage women to throw away the yoke of discomfort and oppression and embrace the feeling of dignity, freedom of choice and success (Ogini, 1996). Feminists in Africa often argue that the meaning attached to motherhood leads to victimisation of women (Akujobi, 2011) and encourage women to contest misconceptions and stereotyping associated with motherhood (Wilson-Tagoe, 1997). Nevertheless, in Africa motherhood remains a blessing, a status symbol and an attribute that is revered in African society (Akujobi, 2011).

Culture

Swazi culture and early motherhood.

Whilst an adolescent girl in the Swazi culture is given “adult” status when becoming a mother, rejection by peers is often experienced. Adolescent mothers are expected to mix with older community members and are denied access to Swazi cultural maiden groups partaking in the annual reed dance festival, where Swazi men choose their virgin wives (Dlamini et al.,
A study done in the Hho-Hho region of Swaziland concluded that Swazi adolescent mothers experienced problems in almost all the dimensions of their lives, that is social, cultural, educational, economical, spiritual and emotional. One of the major problems experienced was the lack of support before, during and after pregnancy by health professionals, teachers, peers, family and the larger community. This leaves adolescent Swazi mothers with feelings of devastation, fear, humiliation, frustration and isolation (Dlamini et al., 2003).

A lack of knowledge on how to prevent pregnancy and how to cope with the tasks of motherhood is one of the main complaints amongst Swazi adolescents mothers as it is a cultural taboo to talk about sex with parents (Dlamini et al., 2003). Ziyane and Ehlers (2006) report that family planning providers reportedly fail to address adolescents’ sexual and reproductive needs, wanting adolescents to practice abstinence, and ignoring the fact that young people are indeed sexually active. Consequently, adolescents do not get sufficient information about contraceptives, even condoms from clinics. This situation is aggravated by the lack of sex education in homes, communities, schools, and social clubs (Ziyane & Ehlers, 2006). Also, in Ziyane and Ehlers's (2006) study discrepancy exists between urban adolescent boys and the rural adolescent boys’ opinions on the use of contraceptives and the girl's involvement in sexual decision making. The rural boys were more prone to rely on cultural beliefs. However, research on this topic is scant and highlights the need for more phenomenological enquiries.
Research methodology—An empirical investigation

Research method and design

This study used a qualitative research method to study human experience and was done from a phenomenological perspective. The aim of a phenomenological design is not to generate theories or models of the phenomenon being studied but to accurately describe the (lived) experiences of the people (Van Manen, 1990). Merriam (2009) argues that a phenomenological research design is effective for studying intense human experiences containing effective and emotional components. The phenomenological research design was therefore most suitable for exploring and describing the experiences of early motherhood amongst Swazi adolescent girls as it is concerned with the human being as a whole and all the parts that contribute to the experience. Although it is possible that human beings experience similar situations in similar ways, every person has different perceptions and interpretations of the shared world (Woldt & Toman, 2005) and has their own subjective reality of the lived experience (Grove & Burns, 2008). The phenomenological approach presents the best viewpoint for the current study, seeing that an individual can be studied as in the case of a narrative approach but also the lived experience of a common life event as perceived by a group of individuals can be studied (Creswell, 2007; Roulston, 2010).

Participants

Purposeful sampling (Struwig & Stead, 2001) was initially used to select adolescent girls according to specific criteria. This method of sampling was specifically applicable to this research since the inclusion criteria ensured that rich detailed information was gathered regarding the early experiences of motherhood. An additional means of data collection known as snowball sampling was used due to the fact that the participants were seen as “hard-to-reach” (Strydom & Delport, 2011), in other words not easily accessible or approachable.
Two of the selected participants suggested other community members as possible candidates for the study, which initiated the process of snowball sampling. These possible candidates were telephonically contacted only after permission was obtained via the referring participant and a face-to-face meeting was arranged to discuss the purpose of the study and whether they would like to take part.

**Inclusion criteria:**

- English second language speaking Swazi girls in the adolescent developmental phase (between the ages of 12 and 21 years), residing in the Nkomazi area, Mpumalanga, South Africa with a first-born child between two and 18 months.

**Exclusion criteria:**

- Adolescent mothers who had premature babies.
- Adolescents who have more than one child.
- Adolescents not suffering from a known disease or disorder, who would be otherwise vulnerable and predisposed to more negative experiences.

Thirteen siSwati-speaking African girls from the ages of 16 to 20 years who are able to speak English, residing within the former homeland area within the Nkomazi municipality in Mpumalanga, South Africa, were selected as participants for this study. The Nkomazi area is densely populated ranging from one hundred to even more than one thousand people per square kilometre for different wards within the area. The participants all come from poor to middle-class households. All participants have access to primary health care clinics, walking distance from their houses, as well as to one of two district hospitals in the surrounding area. About a quarter of the dwellings in the Nkomazi area have piped water to their homes, however generally less than 5% have flushing sanitation systems (Statistics South Africa, 2012b). All participants make use of outside non-flushable toilets and have access to at least one outside water point. Although unemployment and illiteracy is common in the Nkomazi
area with percentages fluctuating within the 40’s and 20’s respectively (Statistics South Africa, 2012b), all participants have at least passed grade 5. All participants have access to electricity, public transport, personal cell phones and television. Eight of the 13 participants indicated that they come from broken homes (i.e. single parented houses, looked after by a grandmother, one or more parent deceased) and five of the 13 girls had returned to school to resume their education at the time the interviews took place.

**Procedures**

Permission was obtained (appendix B) from the Ethical Committee of the North-West University (NWU-0011-10-A1) as well as from the Mpumalanga Health Department (appendix C) to undertake the study. The district hospital’s medical manager was approached to conduct the planned research study by making use of the hospital’s birth registers to identify possible participants. All Swazi adolescent mothers registered in the birth register at the district hospital since September 2010 were considered as possible participants to ensure equality. After permission from the Department of Health was granted, the hospital files were collected and the possible participants were contacted. Unfortunately due to many unforeseen circumstances for example, telephone numbers that had changed, stolen cellphones, and death of some of the patients and so forth, not enough possible participants for data saturation could be found using this means. Some of the already interviewed participants suggested other participants in their communities that matched the criteria, hence the term snowball sampling (Babbie, 2007). Snowball sampling was used until data saturation. Possible participants were telephonically contacted and individual meetings were scheduled either at the district hospital or at the primary health clinics in the surrounding areas, during which the aim of the study and ethical considerations were explained and clarified. Great care was taken to adhere to ethical considerations as suggested by (Mouton, 2001) and (Strydom, 2011) in order to minimize any possible harm, protect the identity of the
participants and respect their privacy. Written consent (appendix D) was obtained before the interviews of 35 – 60 minutes were conducted and the purpose of the study was thoroughly explained. The researcher practiced a phenomenological attitude, setting aside judgment and pre-conceptions about adolescent motherhood and refraining from importing external ideas and beliefs about the topic being studied (Finlay, 2009). This is often referred to as "bracketing" (Joyce & Sills, 2009). The attitude of bracketing allowed the researcher to make sense of the lived experiences without an expectation of what can be found (Joyce & Sills, 2009). The recorded data was transcribed verbatim by the researcher, coded and analysed accordingly.

**Data gathering**

Data collection in phenomenological studies often consists of interviews (King & Horrocks, 2010) either in the form of in-depth interviews (Creswell, 2013) or semi-structured interviews (Barbour, 2007; Smith, 1995), or by making use of other forms of data namely art, music, journals, written work or observations (Creswell, 2013). In this study, semi-structured interviews, consisting of open-ended questions (to allow for free expression on the sensitive topic of adolescent motherhood) were used (Smith & Osborn, 2007). One-on-one interviews were specifically chosen as the method of data gathering as opposed to focus groups to ensure that participants from a vulnerable life stage could feel comfortable in sharing detailed information about their personal experiences without being concerned with peer pressure or judgment from others (Greef, 2011). Smith (1995) argues that semi-structured interviews allow flexibility and are helpful to gain a detailed picture of the participants' perceptions, beliefs and accounts of a specific topic. The semi-structured interviews provided a loose structure of open ended questions to explore the participants' experiences and attitudes as well as exposing the issues or concerns that have not been anticipated by the researcher (Pope, Van Royen, & Baker, 2002). Consistent with the phenomenological approach, the
researcher is not expected to strictly follow the questions but rather to use it as a platform to engage participants and allow them to freely discuss issues that are of importance to them (Smith & Osborn, 2003). Smith (1995) describes semi-structured interviews and the purpose of qualitative analysis as a natural fit. Barbour (2008) amplifies this by stating that when using the interpretative phenomenological approach (IPA) as the method of data analysis, semi-structured interviews are the preferred method of data collection. Although phenomenological studies often only make use of one central question namely – What is the experience of a certain phenomena?”, Kvale and Brinkmann (2009) highlight that more specific studies requires breaking up the central research question in more than one question, thereby implementing semi-structured interviews. The central research question, on what the experiences of early motherhood amongst Swazi adolescent girls are, was divided into four issue-oriented sub-questions. Issue-oriented research questions divide the central research question into subtopics for examination (Creswell, 2007) and address the main concerns and perplexities to be resolved (Stake, 1995). The sub-questions guided the design of the interview guide (Greef, 2011) but could not be reproduced as such, since it would compromise the participants‘ understanding. Instead the sub-questions were paraphrased, and sometimes expanded into a few separate questions as indicated in (Table 1).

Table 1: The Relationship Between the Research Sub-Questions and the 11 Questions on the Interview Guide.

The interview guide (Greef, 2011) consisted of 11 questions which were grouped under the four sub-questions. These questions were chosen after consulting with siSwati-speaking professionals (that work with adolescent girls) who advised that the participants would be reluctant to share feelings and experiences of such a personal nature (especially when answering in English). They further advised that it is culturally unusual for adolescent girls to freely express themselves without being probed to some extent. A flexible interview guide with questions that probe for more in-depth responses was therefore considered more appropriate (appendix E). Furthermore, questions did not address mutually exclusive aspects of the phenomena, thereby enabling the interviewee as well as the interviewer to reflect on the phenomena from different angles. As each of the 11 questions were asked, the question was handed to the participant written in both English and siSwati in order to overcome possible language barriers when it came to the understanding of the verbal questions.

Participants were encouraged to answer in English, but if necessary could express themselves in siSwati (the interviewer has basic siSwati speaking skills helping her to follow the conversation). As suggested by Nieuwenhuis (2011) the researcher made use of reflection, paraphrasing and clarification of answers when siSwati phrases were used in an attempt to keep track and understand clearly what the participants were saying. The interview commenced with an opportunity for the participant to share about herself, thus putting her more at ease, after which the main questions followed. Where the participant struggled to express herself, appropriate open-ended sub-questions were asked and participants were encouraged to answer in siSwati.

All interviews were recorded and transcribed verbatim. Answers given in siSwati were transcribed and translated by a native siSwati speaking person and checked by another skilled siSwati person to ensure reliable translation. No further possible participants were
sought once the interviews produced clear, repeating themes, provided that a minimum of at least five interviews had been completed (Polkinghorne, 1989).

**Data analysis**

The researcher made use of the interpretative phenomenological approach (IPA) to analyse data. This approach falls within hermeneutic phenomenology as discussed by Van Manen (1990) and it is a popular form of data analysis in psychological studies (Smith, 2010). It is different to Moustakas’s (1994) transcendental or psychological phenomenology that focuses more on a description of the experiences of the participants rather than a combination of description and interpretation (Creswell, 2007). Interpretative phenomenology aims to describe, understand and interpret the participant's experiences (Tuohy, Cooney, Dowling, Murphy, & Sixsmith, 2013), investigate how participants perceive a said phenomenon within their particular life context and how they make sense of their personal and social world. IPA is primarily an interpretive technique that explores to a deeper level than other techniques (Hefferon & Gil-Rodriguez, 2011). The in-depth analysis not only allows for a hermeneutical exercise on what is said but also serves as an analysis of other clues emanating from the participant – such that the researcher might gain insight into the experience that the participant themselves might be less aware of (Smith & Osborn, 2007). —-. meaning is central, and the aim is to try to understand the content and complexity of those meanings rather than measure their frequency.” (Smith & Osborn, 2007:66).

According to the researcher’s experience doing counselling with Swazi teenagers, a discourse on feelings and emotions often contains little detail and can be poorly descriptive. This is undoubtedly partly due to the language barrier but might also be attributed to a specific cultural tendency. The researcher foresaw that gathering significant statements (such as is done in Moustakas’ horizontalization) that can be arranged into clusters of meaning and themes would have been a difficult and probably ineffective exercise in this study population.
Therefore a form of data analysis such as IPA that is less dependent on a good choice of descriptive words by the participant, but allows for a wider interpretation, would be more suitable. IPA recognizes a participant as a cognitive, linguistic physical being, for whom the chain of connection between the emotional state and self-expression might be difficult to access. Consequently, it’s up to the researcher to interpret the mental and emotional state from what is said (Smith & Osborn, 2007).

The IPA steps as explained by Smith and Osborn (2007) were used as a guideline with a few important deviations. It is often recommended that in IPA studies, numbers of participants are kept to a minimum (Hefferon & Gil-Rodriguez, 2011). In this study, more participants had to be interviewed to compensate for the poor responses given by some participants. Despite the described efforts to overcome the language barrier, some participants clearly did not understand the questions and gave responses that did not make sense and that were not related to the subject matter. The researcher was forced not to consider such interviews especially when a description of the lived experience was not forthcoming from the interview. Because of this constraint, data saturation was achieved much later (at 13 interviews) than what is normal for IPA studies. The first step of the data analysis was therefore to remove those interviews from the analysis that did not provide a meaningful description of the phenomena. This was the most significant deviation from the traditional methodology but was unavoidable due to the nature of research. The measure of meaningfulness was judged objectively by the researcher considering the three criteria: appropriateness of the response to the question, the linguistic sensibleness of the response and the length of the response. The researcher ended up using 9 of the 13 transcribed and analysed interviews (examples of unsuitable interviews given in appendix F). The above process together with the translation and transcription allowed the researcher to familiarize
herself with the transcripts, an important first step in IPA (Smith & Osborn, 2007). Data was analysed in the following manner:

**Looking for themes.**

Whilst reading and rereading the transcript, any significant or interesting comments were noted in the left margin of the transcribed interviews. This process is described by Smith and Osborne (2007) as similar to a free textual analysis and division of text into meaning units was not required. The comments attempt to summarize, paraphrase or highlight what was said. Through studying a transcript, attention was given to similarities, differences and contradictions in what the participant was saying and this was recorded. This process was followed for the entire first transcript. The researcher then returned to the beginning of the transcript and noted emerging themes in the right margin of the text by transforming the initial comments into specific phrases that capture the essential quality of what was said. When similar themes repeated themselves in the transcript they were noted again as before. See appendix G for an example of a transcribed interview and the first steps of data analysis.

**Connecting the themes.**

The themes identified in the previous step were listed chronologically on a new sheet of paper. After listing they were re-read analytically in order to cluster similar themes together (appendix H). The researcher constantly referred back to the text to make sure the emergent themes were consistent with the primary source. To substantiate the themes, the original text (direct words of the participant) was copied next to the theme using the translated material (appendix I). The themes were presented in table format and logically ordered. At the same time similar themes were clustered together to represent super ordinate themes.
Continuing the analysis with other cases.

The researcher adopted an approach put forward by Smith and Osborn (2007) to use the themes from the first analysis to orient the subsequent analysis. Each of the remaining transcripts was scrutinized in a similar manner to the first; looking for common convergent themes as well as divergent themes. This was a more suitable way of analysis since the researcher worked with a high number of transcripts.

Once all transcripts were analysed and all of the themes tabulated, the researcher had to prioritise the themes. This process involved ranking the themes on factors such as their prevalence within the data, the richness of the supporting phrases and how the particular theme linked with other prominent themes (Smith & Osborn, 2007). The final master table was drawn up containing the ordered themes in a column on the left, followed by a column with transcript references for each of the participants. Appendix J illustrates how the researcher continuously revisited the original transcribed interviews, connected themes from different interviews and reformulated themes in order to draw up the final master table (appendix K) with main themes and sub-themes.

Writing up.

The final phase of the analysis was translating the themes into a narrative. The account had a logical flow, explaining and expanding on each theme in depth, while supporting the statements with verbatim extracts of the transcripts. As the themes were covered the analytic commentary was expanded with links to existing literature supporting the findings.

Ethical aspects

In identifying possible participants, the inclusion and exclusion criteria were specifically selected to allow fair participation in this research study without unfairly disadvantaging possible participants. Seeing that this study focused on the experience of early motherhood, adolescent mothers with premature babies were purposefully excluded.
Prematurity adversely affects the experience of motherhood (Hall, Kronborg, Aagaard, & Brinchmann, 2013; Melo, Souza & Paula, 2014) and would directly place the mother in a vulnerable position. The adolescent mother further more had to only have one child in order to give a sincere account of her experience of adolescent motherhood. The data collection commenced after ethical clearance and permission was obtained from the Ethical Committee of the North-West University (NWU-0011-10-A1) and the Mpumalanga Department of Health. Before conducting the research study the participants were informed that participating in the study was on a voluntarily basis (Neuman, 2003; Struwig & Stead, 2001). This was done telephonically and later in a face-to-face meeting both verbally and in writing. A thorough explanation on the purpose, procedure and extent of the study was given in a written format (Neuman, 2003; Rubin & Babbie, 1997) and verbally discussed with the participants in English and in siSwati. This was done on an individual basis and by making use of an interpreter. The potential advantages, disadvantages and dangers of the research were also discussed. Care was taken not to deceive the participants (Strydom, 2011) into believing that they would directly benefit from the study by for example, receiving a financial incentive or obtaining fame. The indirect benefit of health care workers possibly using the information of their experiences of early motherhood in setting up an educational support program for adolescents with regards to adolescent motherhood was explained. The interview process didn't pose any direct physical, economic or social harm to the participants and any secondary physical harm (e.g., headache or fatigue was overcome by conducting the interviews in a well-ventilated area and allowing participants access to water should they wish to quench their thirst). Participants were further allowed to take important phone calls or attend to their babies if they were present.

The researcher made sure that the participants were psychologically and legally competent to give consent to participate in the study (Terre Blanche, Durrheim, & Painter,
2006) and as suggested by Babbie (2010) this was done by the signing of a written document. Due to the fact that seven of the nine participants were above the age of 18 years, they had the right to give their own consent and therefore parental signatures were not needed. An exception was made for two of the girls aged 16 and 17 who indicated the desire to participate in the study in order to give voice to their experiences as adolescent mothers but who preferred not to involve their caretakers. Human-Vogel's (2007) policy guidelines on the inclusion of minor children in research investigations was considered and the researcher considered the possible risks and benefits of these two girls participating in the study. One of these two girls indicated the desire to participate in the study but pointed out that the financial and time constraints of having to return home from the clinic to meet with her caregiver to sign the consent letter would disqualify her from participating in the study. The other girl indicated that it might cause unnecessary friction between her and her parents but that she wished to participate in order to make her "vote count". Based on the virtues of beneficence (Grinnell & Unrau, 2011) and equality the researcher argued that all adolescent mothers should have a fair chance to participate in the study and consequently the researcher argued that the risk of participation for these two adolescents was negligible and the indirect benefits for the adolescent themselves outweighed the risks involved and therefore an exception was made.

The researcher ensured the participants of right to privacy and confidentiality and emphasized that personal information regarding identity would only be known to the researcher (Struwig & Stead, 2001) and this information will be kept for five years in a safe place (locked cabinet) which is only accessible to the researcher (Flick, 2009). Confidentiality was further maintained by assigning a code to each participant. By doing this, the participants' personal details were not used during the use of interpreters' transcription of the Siswati interviews. It was explained to the participants that examiners
and certain supervisors from North-West University would have access to the transcribed interviews; however without knowing the identity of the participants in order to evaluate the researcher’s work. It was also explained that names would not be mentioned in any article or research report, to ensure confidentiality.

Responsibility was taken in the setting up and structuring of the interview to avoid physical or emotional harm to the participants (Babbie, 2010; Flick, 2009; Strydom, 2011). The researcher took great care in respecting the participants’ culture and social practices by consulting Swazi professionals working with adolescent girls in the setting up of the questionnaire and the appropriateness of the content of the questions in order to avoid any possible harm. Questions were fairly posed to the participants in both their first and second languages (i.e. siSwati and English). One-on-one interviews were purposely used to ensure participant privacy and to allow for freedom of expression (Greef, 2011). Any emotional harm was minimized by highlighting that nobody was under obligation to answer questions that caused discomfort as well as the right to withdraw at any given moment during and after the completion of the interview (Strydom, 2011). The researcher provided the participants with her cellphone number should they decide after the interview had been conducted to withdraw from the study. Keeping in mind that talking about the experience of motherhood might be a sensitive topic for some of the adolescents, the possibility of arranging a debriefing session after the conclusion of the research study to resolve any misconceptions that might have surfaced during the study was offered (Strydom, 2011). The participants’ benefits were maximized by providing them with therapists’ numbers at the nearest district hospital that could assist them with information on child support and development and possible therapeutic treatment for any child-related problems. For the participants’ convenience, an appointment could also be scheduled at any primary health clinic seeing that
a multi-disciplinary team consisting of occupational therapists, physiotherapists, speech therapists and dieticians offer outreach services at the clinic on a monthly basis.

During the conduction of the research study, the researcher, a registered occupational Therapist, was constantly aware of her ethical responsibilities and was adequately equipped and skilled to conduct the planned research (Strydom, 2011). The researcher took great care to avoid judgment or have her personal values influence the research findings (Thomas & Hodges, 2010). This was done by writing down and reflecting on any preconceived ideas the researcher had on adolescent motherhood. Throughout the research process, any judgemental ideas were acknowledged and neutralized through discussion with other professionals. Transcribed interviews were given to more than one independent researcher to comment on in order to avoid biased interpretation.

The results of the study were released in the format of a written article (Strydom, 2011). Recognition was given to all sources used to avoid plagiarism (Babbie, 2010) and the researcher reported honestly about the limitations and errors that occurred during the research process (Strydom, 2011).

**Trustworthiness**

The trustworthiness of research is integral to the legitimacy and credibility of its findings. To warrant trustworthiness, the propositions of Lincoln and Guba, (1985) were used (Table 2), which include credibility, dependability, transferability and conformability.
Table 2: Strategies for ensuring trustworthiness

</tbody>
</table>
Summary

In section A part I the researcher gave a discussion of the rationale and motivation of the study, formulated the research question and aim of the study and presented an introductory literature review of the main concepts that were identified. The research methodology, ethical aspects and trustworthiness were also discussed.

Conclusion: Section A Part I

The aim of section A Part I was to give an overview of the problem statement, discuss the rationale of the study and define important concepts and previous research on the experiences of adolescent motherhood. The research methodology, ethical considerations and trustworthiness were also given attention. Section A Part II will provide information on theories and models underpinning the study of adolescent motherhood.
Section A Part II: Integrated literature study

This section aims to give an overview of the theoretical framework and existing literature with regards to adolescence and motherhood and the different theories and models applicable to this topic through discussing Ericson’s theory of adolescent development, Keyes’s model of well-being, the ecological model of Bronfenbrenner and phenomenology. These theories are defined, explained and contextualised within the parameters of this study in the sub-sections below.

Adolescence

The nature of adolescent development

Adolescence is distinctly known as the phase in which the body changes and prepares for sexual maturity with increased production of gonad hormones. Girls typically show physical signs of puberty earlier than boys with menarche [the first menstruation] being the most dramatic event in their sexual maturity (Sigelman & Rider, 2011). Girls often react to the maturation process with mixed feelings and worry about their self-image, their physical appearance and their skills and abilities. Youths within the adolescent phase of life are known to be ignorant of reproductive issues (Macleod, 2003), taking part in risky sexual behaviour (unprotected sex, sex with a non-marital or non-cohabiting partners). According to the 2011 State of the World’s children report, adolescent boys between the ages of 15–19 years are more likely to engage in higher risk sex than adolescent girls of the same age, however the risk of HIV infection is higher amongst adolescent girls than adolescent boys (UNICEF, 2011).

With regards to cognition the early stages of adolescence are characterized by concrete thinking abilities that later develop into abstract thinking and reasoning in the middle and late stages of adolescent hood (Collins, 2008). Socially, peer relationships start influencing adolescent decision-making processes and shaping identity.
Choices about morals and values are established and adolescents begin defining their own uniqueness (Collins, 2008; UNICEF, 2011). In terms of behaviour, early adolescence is characterized with experimenting with new behaviour, while youth in the middle stage of adolescence are more prone to risky behaviour for example, drug and alcohol use, eating disorders, sex, and so on, (Collins, 2008), which further develops into the assessment of their own risk-taking as they get older (Sigelman & Rider, 2011). Not only do adolescents need to adjust to all the changes but they also need to start making choices about careers and future. One of the pioneers of American psychology in the early 1900s, G.S. Hall, was of the opinion that young people struggle to adjust to the confusing and dynamic process of adolescence and therefore are experienced by others as rebellious, stressed, emotional and prone to inner conflict (Collins, 2008). It is evident that the adolescent developmental phase constitutes a period of great change, challenges and development particularly in a girl's life and should not be taken for granted when doing research with this particular age group.

**Main theorist: Erikson**

Erik Erikson, a prominent developmental theorist of the 1950s, formulated a theory of human development that envelops the entire life cycle span from infancy and childhood through to old age (Saddock & Saddock, 2003). Erikson used the term "crisis" to suggest a series of internal conflicts that are linked to eight developmental stages. According to Erikson's theory, if a person does not successfully resolve each "crisis" in each life stage, it will influence their personal identity and future development (Saddock & Saddock, 2003). If a child masters each psychosocial "crisis" in each stage, he/she will gain new ego strength (Sigelman & Rider, 2011). The eight stages can be summarized as (1.) trust versus mistrust; (2.) autonomy versus shame and doubt; (3.) initiative versus guilt; (4.) industry versus inferiority; (5.) identity versus role confusion; (6.) intimacy versus isolation; (7.) generativity versus stagnation; (8.) integrity versus despair (Sigelman & Rider, 2011).
The fifth stage (12–20 years) corresponds to adolescence, when the child struggles between identity and role confusion. Erikson describes adolescence as being a period where the child tries to develop her own sense of identity (Sigelman & Rider, 2011). During adolescence the child is faced with questions of who she is, how she fits into the world and how the world's view of her correlates with how she feels about herself. Childhood fantasies and roles are not appropriate anymore, yet the adolescent has not yet attained adult status (Saddock & Saddock, 2003). It is typically during adolescence that the individual will defend against role diffusion by joining a cult or clique or identifying with her heroes (Saddock & Saddock, 2003). If the adolescent receives proper encouragement and reinforcement through personal exploration, she will learn to successfully deal with the “crisis” during adolescence and will have the freedom to associate with others without losing her own identity. This will result in a strong sense of self and a feeling of independence (Cherry, 2014) and will lead the adolescent into attaining fidelity as a virtue which will enable her to deal with conflicting issues like intimacy versus isolation in the next stage of life (Oswalt, n.d.). If there is a loss of direction and purpose she might experience role confusion and an identity crisis. The adolescent might be unsure of her beliefs and desires and might experience insecurity and confusion (Cherry, 2014). Role confusion—not knowing who you are—can manifest in several difficulties such as running away, psychosis, questioning gender role and confused sexual orientation (Saddock & Saddock, 2003) and becoming socially cut off or isolated (Oswalt, n.d.).

Erikson’s theory of adolescent development has particular bearing on the experience of adolescent motherhood as adolescent motherhood might have the ability to hamper her in attaining the necessary ego strength during the adolescent phase, in order to establish an autonomous sense of self and resolve the next stage of intimacy (Hurlbut, Culp, Jambunathan, & Butler, 1997). Adolescent mothers are faced with dealing with different life
stages simultaneously (Sadler & Cowlin, 2003) and are forced to cope with the stage of
generativity, which has to do with parenting, before they are necessarily ready for it (Hurlbut et al., 1997). According to Erikson’s theory and the literature, this puts their parenting skills at risk. Furthermore it might influence the ability to successfully attain fidelity by making and respecting commitments to another person (Saddock & Saddock, 2003). Erikson was of the opinion that one must know oneself in order to be able to love another person. The young adult with a distorted sense of self might find it difficult to commit to long term relationships or might become overly dependent on a partner as a way of finding her own identity (Sigelman & Rider, 2011); and previous research also suggested that adolescent mothers were cautious with pursuing new romantic relationships (Sodi & Sodi, 2012).

Adolescents and well-being (Keyes’s model)

Keyes (2002) argues that mental health or well-being measures psychological, emotional and social well-being. These three dimensions of well-being will be discussed in short.

**Psychological well-being.**

Psychological well-being refers to the subjective and personal account of one’s satisfaction and functioning in life and consists of six dimensions namely (1) self-acceptance—positive evaluation and attitude towards the self, liking the different parts of the self; (2) positive relations with others—the ability to form quality, trusting relationships with others; (3) personal growth—experiencing continued self-development and seeking challenges; (4) purpose in life—experiencing one’s life as having meaning; (5) environmental mastery—the ability to effectively manage one’s life, and; (6) autonomy—being self-determined and being guided by internal values and standards (Keyes, 2005; Ryff & Keyes, 1995). Psychological well-being does not only measure whether a person is coping with life, but actually to what extent they are flourishing (Keyes, 2002).
Emotional well-being.

Keyes (2002) defines emotional well-being as a group of symptoms reflecting the existence or non-existence of positive feelings about life. Emotional well-being is measured by an indication of the presence of positive affect, the absence of negative affect and persons’ satisfaction with life.

Social well-being.

Social well-being typifies the social and public criteria that persons use to evaluate every-day functioning in society (Keyes, 2002). Keyes (1998) describes several social challenges experienced and constructed these different social dimensions into a measurement scale in order to establish if individuals see themselves thriving in their social lives (Keyes, 2002). The first dimension described by Keyes (1998) is social integration” and measures whether a person feels as if they are part of society and what the quality of their relationship is with the community that they live in. Secondly the degree of social acceptance” is measured. This implies an understanding of the nature and qualities of society as a whole and a belief that others can be trusted and have the ability to be hard-working and kind. Keyes (1998) argues that social acceptance of others might be closely linked to self-acceptance. Social well-being is also dependent on social contribution” and measures whether persons experience themselves as valuable to society and whether they feel as if they are contributing to the world (Keyes, 1998). Fourthly, social actualization” refers to the evaluation of the potential and evolution of society. Socially healthy people are more confident about the future of society and see themselves as potential recipients of social growth (Keyes, 1998). Lastly, in order to evaluate social well-being, a person’s social coherence” should be kept in mind. In other words a socially healthier person is someone that is interested in how the world that they live in is organized, how the world works and how to make sense of life (Keyes, 1998).
Ecological model: The role of context

The ecological model of Urie Bronfenbrenner argues that the entire ecological system in which growth occurs should be considered in order to understand human development (Bronfenbrenner, 1994). In other words there is a dynamic, complicated interaction between humans, objects and their environment and it is this reciprocal interaction that is responsible for growth (Merrick, 1995). Bronfenbrenner (1994) identifies five nested environmental systems with which an individual interacts: the microsystem, mesosystem, exosystem, macrosystem and chronosystem. Each of these systems will be defined and the relevance of this in the study of adolescent motherhood will be mentioned.

Microsystem.

The microsystem refers to the direct environment in which persons live, their interpersonal relationships, their roles and the activities of daily life in which they participate (Bronfenbrenner, 1994). The theory argues that people are not merely recipients of the experiences when interacting with people and institutions from their microsystem, since all the different microsystems contribute to the construction of this environment (Sincero, n.d.). For the adolescent mother these settings include her interactions with her family, home, school, friends and church where she plays the role as daughter, mother, sister and friend. In exploring the experience of early motherhood amongst Swazi adolescent girls, one should consider how this experience has influenced her relationship with her family, her school and her peers. Her experience of motherhood can also be directly affected by the social support she receives from her microsystems and the reactions to her situation.

Mesosystems.

The mesosystem consists of the interactions and processes that take place between two or more settings / microsystems of which the developing person is part of (Bronfenbrenner, 1994) for example, the relations between the adolescent mother’s home and
school, the interaction between the neighbourhood and the school and alike. The support that the adolescent experiences at home can influence whether she will continue with school or not (Lehana & Van Rhyn, 2003). Some countries like South Africa allow adolescent mothers to return to school (Bhana et al., 2010) which might have an impact on their overall experience of motherhood and might influence their future career possibilities.

**Exosystem.**

The exosystem is the processes in which the developing person is not actively involved in but that indirectly influence the developing person (Bronfenbrenner, 1994). Many adolescent mothers are dependent on their parents and families for financial support (Spear, 2004) and therefore an impact on one of the parent’s occupations can indirectly influence the adolescent mother as well.

**Macrosystem.**

The macrosystem refers to contextual patterns of systems that exist at the level of the culture or the subculture as a whole (Reifsnider, Gallagher, & Forgione, 2005). These contextual patterns include a person’s belief systems, language, race, socio-economic status, ideology and ethnicity. Culture plays a specific role in one’s experience of motherhood (Akujobi, 2011) and therefore the experience of early motherhood amongst Swazi adolescent girls might be different from the experience of girls from other races and cultures. The socio-economic status of the adolescent girls in this study should also be kept in mind as it could influence the way in which early motherhood is experienced. In South Africa adolescent mothers can apply for a child-support grant which can assist with the financial expenses of the child but there are several criteria to which a mother must adhere to in order to be able to qualify for the grant. For example, the mother must prove that she is the primary care-giver of the child and she must have proof that she is a South African citizen. (DSD, SASSA, &
The experience of early motherhood amongst Swazi adolescent girls (UNICEF, 2012). Research indicates that the minority of adolescent mothers do however end up receiving grants (Makiwane, 2010).

**Chronosystems.**

The chronosystem includes the transitions in one’s lifespan and events occurring in the context of passing time. This may also involve the socio-historical contexts that may influence a person (Sincero, n.d.). In South-Africa for example, the effect of apartheid should be kept in mind and how it influenced the family structures, the socio-economic status and the employment of the family in which the adolescent mother grew up (Bronfenbrenner, 1994).

In summary, according to Bronfenbrenner’s ecological perspective, the quality of environmental and contextual influences will influence the adolescent’s development (Reifsnider et al., 2005) and experiences of early motherhood.

**Motherhood**

**Mother-child attachment**

Being a mother constitutes several responsibilities (Mercer, 2004). A child’s first contact is with his/her mother and this mother-child interaction is pivotal for shaping and forming a child (Barkin & Wisner, 2013). Bowlby’s (1954) work on attachment suggests that the child’s relationship with the mother (or mother figure) has irreversible mental health consequences for the child, either positively or negatively. Attachment can be defined as “an emotional bond formed between an infant and one or more adults”, usually the mother (Reber et al., 2009, p. 69). The attachment styles of children are especially important since failure to form a good attachment with a parent can result in the children’s sense of self being incomplete, fragmented and with a limited sense of autonomy (Hughes, 1997). The implication is that the ability to handle difficult situations as well as the relation to others and the world around them both as children and as adults is influenced (Hughes, 1997). It can
therefore be said that mothers make a remarkable contribution to society (Logsdon et al., 2006) as well as the family unit.

**High functioning mothers**

Barkin, Wisner, Bromberger, Beach, and Wisniewski (2010) describe a high functioning mother as someone who has adequate social support, is able to take care for her own mental and physical wellbeing, takes care of her child, attaches to her child, juggles her various responsibilities and adapts over time. In order to fulfil all the demands of being a mother, it is essential that a mother takes proper care of herself by ensuring that she follows healthy eating habits, taking time out for herself when necessary, making sure she receives adequate sleep and looking after her physical appearance (Barkin & Wisner, 2013). It seems that high functioning mothers are important with reference to their personal well-being as well as their children’s overall healthy development.

**Positive experiences of motherhood**

Many studies of women's post-natal experiences tend to highlight the negative experiences, yet many women experience motherhood as positive. A study done with 1285 women approximately six weeks post-partum indicated that two-thirds gave the maximum score of five for enjoying looking after the baby and 79% for being proud of being a mother (Green & Kafetsios, 1997). Motherhood has also been associated with greater positive mental health outcomes such as higher levels of life satisfaction (Hansen, Slagsvold, & Moum, 2009) and even though parenting can be stressful, it is rewarding (Evenson & Simon, 2005).
Culture

South African cultures

South Africa is a multi-ethnic society characterized by its diversity, having 11 official languages, the most of any country in the world ("Most official languages (country)", n.d.) These are: English, Afrikaans, isiZulu, isiXhosa, Sesotho, Setswana, Sepedi, Xitsonga, siSwati, isiNdebele and Tshivenda ("South Africa Country Profile", 2013). South Africa is often referred to as the rainbow nation with a variety of traditions, religions, customs and beliefs (Argent & Westoby, 2009). It is a relatively young democracy, having abolished *apartheid* which restricted economic, education and democratic rights to the minority white population in 1994 (Steinberg, 2014). Since then, all South Africans have enjoyed equal rights and have triumphed in having a peaceful transition of government and reconciling the injustices of the past (Sitze, 2013). Economic inequality remains a massive problem with 62% of the population having a monthly income of less than R800. Of these, 86% are Black Africans (SuperCross version 8.0.2.32, 2011). Also with regards to education, great inequalities remain. Grade 10 represents the median education level (including the siSwati speakers) compared to grade 12 (for English speakers). Of the 51 million people in South Africa, 2, 5% of them come from the Swazi culture (SuperCross version 8.0.2.32, 2011). This study focused specifically on adolescent girls in South Africa from the Swazi culture.

Swazi culture.

The literature on Swazis was found to be limited and information on the Swazi culture was from research projects executed a couple of years ago. Swazis are an ethnic group that belongs to the Bantu language group in Africa. siSwati, which is related to the Zulu language, is their mother language. By the nineteenth century Swazis were threatened by the Zulu nation in the south and therefore relocated further north to the region that is today known as Swaziland (Healey, 2011). The country’s name is derived from the first king of the modern
Swazi state, King Mswati Dlamini II (1840-1865). Swaziland is a small country in south-eastern Africa nearly completely surrounded by South Africa except for the north-eastern region, which borders Mozambique. Over the years Swaziland has been greatly affected by the HIV/AIDS epidemic and drought, poverty and starvation have brought much suffering to the country (Healey, 2011). Traditionally, the Swazi people are known as farmers but many have established themselves in other countries to find better job opportunities. Since the study area is geographically adjacent to Swaziland, and since the study population speaks the same language as is spoken in Swaziland, it increases the likelihood that studies from Swaziland would have similar findings in the Nkomazi municipality.

Traditionally Swazi families are male dominated, yet Swazi women form the backbone of the homestead (Ginindza, 1989). Swazi women are hesitant to embrace western biomedical medicine and many fear losing their fertility through the use of contraceptives (Ziyani 2003). Traditional practices surrounding labour are strongly adhered to in preference to biomedical control (Thwala, Jones, & Holroyd, 2012). The rate of contraceptive use in Swaziland is as low as 10% (Ziyane & Ehlers, 2006) despite sexual activity among teenagers being common at more than 50% (Ministry of Health and Social Welfare 2001). These statistics are in conflict with the traditional custom of ‘umcwasho’—the custom of chastity and sexual restraint—which has been highly valued by Swazis for decades. This custom forbids young, unmarried girls engaging in any form of sexual activity for a specified period, the length of which is determined by the king on a national or regional level. The Swazi elders and parents are known to be strict and conservative with regards to sexual activity amongst the youth who have reached puberty (Van Rooyen & Hartell, 2010).

Culturally, Swazi men are awarded higher status than Swazi woman (Dlamini et al., 2003) especially when it comes to sexual decision making (Ziyane & Ehlers, 2006). The
same behaviour in siblings of different sex is treated differently depending on the gender of the child. A father might praise his son for dating more than one girl simultaneously, whilst chastising his daughter for the same behaviour as it could decrease her bridal value (lobola) offered to the father by her future husband. If the daughter should fall pregnant out of wedlock, it would be seen as a disgrace to the family and she and her child would be insulted and called bad names (Dlamini as cited in Malherbe, Kleijwegt, Koen, & Unisa, 2001).

In the traditional Swazi culture an infertile Swazi woman is seen as a disgrace and stigmatized in society (Gule, 1994; Russell, 1993; Ziyane & Ehlers, 2006). Infertility has been seen as sufficient reason for men to divorce wives or engage in sexual encounters with other younger woman that can bear children on behalf of his wife (Women and Law in Southern Africa cited in Ziyane & Ehlers 2006). It is desirable to have many children, since off-spring are seen as a form of life insurance or a family resource as they guarantee support in old age (Gule, 1994). Children are furthermore important for determining and maintaining the political and social position of the family (Ziyane & Ehlers, 2006). Where “lobola” (bridal money) is paid, the husband’s family expects the woman to bear a minimum of six children (Ziyane & Ehlers, 2006). Male babies are more desirable than female babies as a male baby will secure the family name and can take over the father’s responsibilities. This implies that Swazi women may not control fertility until a boy is born. Cultural expectations can limit the use of contraceptives and pressure women into falling pregnant at a younger age to prove fertility (Ziyane & Ehlers, 2006).

Rearing a child when one is not working brings about financial stress on the family. For more traditional Swazi families the financial burden seems to be less of a stressor seeing that dealing with adversities in life is a common occurrence. Families in the transitional phase from a traditional lifestyle to a more Westernized lifestyle seem to experience more
emotional difficulties when faced with adolescent motherhood. The parents of these girls often have high hopes and big future dreams for their daughters in terms of education, work and lifestyle which appear to be shattered once the girls fall pregnant (Dlamini et al., 2003).

It is interesting to note that in recent research done with adolescent boys and girls in Swaziland, the adolescents are starting to think differently about sexual matters than what was traditionally been expected. Nevertheless, their cultural predisposition remains strong. Adolescent boys indicated that although they maintain the belief that Swazi men are the sole decision makers in sexual matters, they are of opinion that Swazi women should only commence childbearing activities at the age of 21 years or older (Ziyane & Ehlers, 2007). Male adolescents preferred a family of two to four children and the adolescent girls preferred two or three.

**Phenomenology**

Seeing that this research is looking at the lived experiences of early motherhood amongst Swazi adolescent girls, it is necessary to shortly clarify the phenomenological approach as to investigate the subjective understandings of humans.

**Background on phenomenology**

Phenomenology can be defined as a philosophical doctrine that studies immediate experience (Reber et al., 2009) and the science of essential being (Clark, 2007). This perspective recognizes the value of human experience. Since the original contribution by Husserl, many followers of this discipline have added their own perspectives and ideas to this developing science, so that today, there are various approaches and methods within the science (Clark, 2007). Finlay (2009) argues that phenomenological researchers generally agree that — . . our central concern is to return to embodied, experiential meanings. We aim
for fresh, complex, rich descriptions of a phenomenon as it is concretely lived” (Finlay, 2009, p. 6).

**Lived experience**

Phenomenology also draws on the works of Alfred Schutz who explained how the life world of a subject (a person’s conscious experience of everyday life) is experienced and developed by them (Schwandt, 2007). The focus is on any events, happenings and experiences that a person can see, hear, touch, smell, taste, feel, intuit, know, understand, or live (Seamon, 2013) and how the person relates to them (Lester, 1999; Reber et al., 2009) in the here-and-now (Joyce & Sills, 2009). Van Manen (1990) refers to these conscious experiences as “lived experiences”. The inquirer therefore tries to describe the phenomena that the person is experiencing by trying to stay as close as possible to the lived experience of the person (Thomas, 2004) and to give a composite description of “what” and “how” a person experienced a specific situation or event rather than giving an analysis or explanation of that event (Moustakas, 1994). Creswell (2007:57) explains a phenomenological research paradigm to be one which “... describes the meaning for several individuals of their lived experiences of a concept or a phenomenon.” This means that the aim of this outlook is therefore to describe the essence of what all the subjects, for example, adolescent Swazi mothers under investigation, have in common (early motherhood) as they experience a situation (Creswell, 2007).
Types of phenomenology

Giorgi, A. identified five main phenomenological methods being used in psychology in the first decade of the twenty first century (Giorgi & Giorgi, 2007):

1. Goethean pre-philosophical experimental phenomenology
2. Grass-root phenomenology
3. Interpretive phenomenology
4. Descriptive pre-transcendental Husserlian phenomenology
5. Husserlian phenomenology based on the return from a transcendental.

For the purpose of this study hermeneutic phenomenology (Van Manen, 1990) will be highlighted and summarized as this was the type of phenomenology method utilized for this study.

Hermeneutic phenomenology as described by van Manen

Van Manen (1990) focuses on the lived experiences of individuals and interpreting the “texts” of life (hermeneutics). Although he doesn’t approach phenomenology with rigid rules or structure, he discusses phenomenological research as a “dynamic interplay” among six research activities (Creswell, 2013). Researchers first turn to a phenomenon that thoroughly interest them e.g. adolescent motherhood and then start reflecting on the essential themes and what the lived experiences consists of. While maintaining a strong relation to the topic of inquiry a balance between the individual experiences and the whole is described. The process is both descriptive and interpretive in nature as opposed to Moustaka’s (1994) transcendental phenomenology which is focused less on the researcher’s interpretation and more on the description of the participant’s experience. In hermeneutic phenomenology the researcher helps the participant to make meaning of what is experienced, reading between the lines and allowing the ordinarily hidden aspects to become more evident (Creswell, 2013).
Conclusion: Section A Part II

The aim of section A Part II was to give an overview on literature covered in this study. The findings of this study are shared in Section B in article format in compliance with the authors’ instructions as specified by the selected journal, Journal of Psychology in Africa. Section C serves to unite sections A and B with a critical discussion of the research findings and includes the research limitations and recommendations for future research.

Abstract

The aim of this research was to explore and describe the experiences of early motherhood amongst Swazi adolescent girls. Positive psychology formed the theoretical framework. A qualitative phenomenological design was used, and nine participants from the ages of 16 to 20 years and residing in Mpumalanga, South Africa, were selected through a process of snow-ball sampling. Data was collected by means of semi-structured interviews, and analyzed using the interpretative phenomenological approach (IPA). Five main themes were identified: (a) The influence of emotions; (b) Social support during early adolescent motherhood; (c) Challenges experienced during early motherhood; (d) Personal growth; and (e) Resilience. The findings indicate that early motherhood entails both positive and negative experiences for Swazi adolescents. Although the motherhood experience was challenging, positive adaptation through social acceptance and support enabled resilient overcoming for some. Recommendations to enhance the well-being of Swazi adolescent mothers are given.

Keywords: Swazi, adolescents, motherhood, phenomenology, positive psychology, adolescent pregnancies
The experience of early motherhood amongst Swazi adolescent girls

Adolescent pregnancies and early motherhood are rife all around the world, a dilemma that exists across all cultures in both developed and developing countries (UNFPA, 2013). Research shows that although overall fertility in South Africa is decreasing, adolescent pregnancies are declining at a slower pace despite freely available contraceptives at state health facilities (Maholo, Maja, & Wright, 2009; Panday, Makiwane, Ranchod, & Letsoalo, 2009). Almost one in five women from developing countries fall pregnant before they turn 18, and up to one in four in East and Southern Africa (UNFPA, 2013b). Poorly educated, impoverished and rural adolescent girls have a higher risk of becoming pregnant than wealthier urban girls (UNFPA, 2013a). In Swaziland, 28% of girls became pregnant before their eighteenth birthday for the time period 2000 to 2009 (UNICEF, 2011). Compared to the world average of 15% (calculated in the same study), Swazi girls seem to be especially prone to adolescent pregnancies making this cultural group particularly valuable for research purposes.

The transition to motherhood is a life changing situation for any woman (Paris & Helson, 2002), but even more so if it occurs during adolescence, as motherhood and the life stage of adolescence can be in conflict with one another (Sadler & Cowlin, 2003). While the adolescent mother is still in the process of figuring out who she is in the world and amongst her peers (Sigelman & Rider, 2011), her newly acquired maternal role might hinder her developing identity (Sadler & Cowlin, 2003). Adolescent motherhood can therefore give rise to several social and psychological problems (Richter & Mlambo, 2005) for the adolescent mother and her baby.

Adolescent mothers have a higher risk for post-natal depression (Figueiredo, Bifulco, Pacheco, Costa, & Magarinho, 2006), which in turn could influence parenting skills (Reid &
Meadows-Oliver, 2007) and result in a greater likelihood of poorer attachment styles with their children (Flaherty & Sadler, 2011). When secondary school learners become pregnant, it often results in schooldrop-out which entails numerous problems, such as limited future career options and lowering socio-economic status (Grant & Hallman, 2006; Lehana & Van Rhyn, 2003; Macleod, 1999); financial difficulties (Spear, 2004); problematic relationships with families, friends and boyfriends (Rolfe, 2008; Spear, 2004); feelings of self-blame, sadness, isolation, and lack of interest (Sodi & Sodi, 2012); and losing out on childhood experiences (Rolfe, 2008).

Research indicates that children of adolescent mothers are often born prematurely (Panday et al., 2009) or have low birth weight (Hoffman, 2006), and are prone to developmental and intellectual delays (Whitman, Borkowski, Keogh, & Weed, 2001). Daughters of adolescent mothers are more likely to become adolescent mothers themselves, and sons of adolescent mothers are more likely to be imprisoned (Hoffman, 2006). Also, children of adolescent mothers are more prone to dropping out of school, have poorer academic performance and poorer school attendance (Kirby, Laris, & Rolleri, 2007; Panday et al., 2009). Although the afore-mentioned issues must be viewed from a 21st century perspective, and the role of culture and context should be considered, it is evident from previous research that adolescent motherhood poses a number of challenges that require many compromises and adjustments (Kaufman, De Wet, & Stadler, 2001).

Not all girls necessarily experience adolescent motherhood as negative and studies amongst different cultural groups have indicated that some adolescents have positive experiences in becoming mothers (Chohan, 2011; Furstenberg, Brooks-Gunn, & Morgan, 1990). Lehana and Van Rhyn (2003) show that unmarried adolescent girls in Maseru reported acceptance and support from families, boyfriends, friends and community members
during their pregnancies. Chohan (2011) indicates that the experience of positive emotions, such as happiness, excitement and a sense of fulfilment were an integral part of motherhood for the adolescents under study. Macleod (2003) emphasizes how teenagers may see becoming a mother as a pathway to the desired status of adulthood. Furthermore, adolescent girls from Swaziland are of the opinion that starting childbearing whilst still being a teenager is ideal and would enable a woman to bear the optimum number of children in her lifetime (Ziyane & Ehlers, 2006).

Besides the fact that there is limited research on adolescent motherhood in South Africa in general, a void remains in the literature regarding the Swazi cultural group and their personal, subjective experience of adolescent motherhood. The question arose as to how Swazi girls experience early motherhood. By exploring and describing the lived experiences of early motherhood amongst Swazi adolescent girls in the Nkomazi area of Mpumalanga province, first-hand information from the adolescents themselves can be obtained in order to gain an understanding of their experience of early motherhood. This information can be used in future to provide guidelines for an educational pregnancy prevention programme in South Africa by increasing awareness of the challenges associated with motherhood, the impact it has on the lives of adolescent girls and the importance of responsible motherhood. Furthermore the information can also provide guidelines for establishing a support programme that will equip the girls for the task of early motherhood.
Method

Aim of the study

The aim of the study was to explore and describe the experience of early motherhood amongst Swazi adolescent girls highlighting both positive and the negative experiences. The participants were encouraged to reflect on what they experienced and how they experienced the early period of adolescent motherhood (pregnancy included).

Design

In this study, a qualitative approach with a phenomenological method of inquiry was used since it provides a basis for both an individual as well as a group of individuals with a common life event to be studied (Creswell, 2012; Roulston, 2010). The phenomenological approach allowed the researcher to focus on the “how” of the adolescent Swazi girls’ personal feelings and convictions of motherhood, in the present moment, rather than trying to interpret the reasoning or the “why” behind the lived phenomena (Joyce & Sills, 2009).

Participants and setting

Purposeful and snowball sampling was used (Strydom & Delport, 2011) as an effective means of data collection. Nine Swazi girls between the ages of 16 and 20 years who are able to speak English and residing within the former homeland area of Nkomazi municipality in Mpumalanga, South Africa, were selected. The Nkomazi area is densely populated ranging from one hundred to even more than one thousand people per square kilometer for different wards within the area. The participants all came from poor to middle-class households and had access to primary health care clinics, walking distance from their houses, as well as to one of two district hospitals in the surrounding area.
About a quarter of the dwellings in the Nkomazi area have piped water to their homes, however generally less than 5% have flushing sanitation systems (Statistics South Africa, 2012). All participants made use of outside non-flushable toilets and had access to at least one outside water point. Although unemployment and illiteracy is common in the Nkomazi area with percentages fluctuating within the 40’s and 20’s respectively (Statistics South Africa, 2012), all participants had at least passed grade 5. All participants had access to electricity, public transport, personal cell phones and television. In accordance with the inclusion and exclusion criteria, all the participants had only one child between the ages of two and 18 months and the child was not born prematurely. The participants did not have a history of a chronic illness.

**Data gathering**

Semi-structured interviews, consisting of open-ended questions were used. Smith (1995) argues that semi-structured interviews allow flexibility and are helpful to gain a detailed picture of the participants' perceptions, beliefs and accounts of a specific topic. Smith (1995) describes semi-structured interviews and the purpose of qualitative analysis as a natural fit. Barbour (2008) amplifies this by stating that when using the interpretative phenomenological approach (IPA) as the method of data analysis, semi-structured interviews are the preferred method of data collection. One-on-one interviews were specifically chosen to decrease any possible emotional or psychological harm. This was done to ensure that participants from a vulnerable life stage could feel comfortable in sharing detailed information about their personal experiences of adolescent motherhood without being concerned with peer pressure or judgment from others (Greef, 2011). The interview guide (Greef, 2011) consisted of 11 questions. In order to overcome possible language barriers as to the understanding of the verbal questions, the questions were written in both English and siSwati and were shown to each participant during the interview (See appendix E).
Participants were encouraged to answer in English, but if necessary could express themselves in siSwati. All interviews were recorded and transcribed verbatim. Answers given in siSwati were transcribed and translated by both a native siSwati speaking person and checked by another skilled siSwati person to ensure reliable translation.

**Procedure and ethical concerns**

Permission to conduct research was obtained from the Department of Health in Mpumalanga and approval was obtained from the Ethics Committee of the North-West University for this project (approval number: NWU-0011-10-A1). A thorough explanation on the purpose, procedure and extent of the study was given to the participants in a written format (Neuman, 2003; Rubin & Babbie, 1997) and verbally discussed in English and in siSwati. All participants gave written informed assent (two participants were only 16 – 17 years old) and those older than 18 years gave written informed consent prior to their participation with assurance that participation was voluntary, anonymous and confidential. To ensure further confidentiality, a code was assigned to each participant and therefore personal details were withheld from any other involved parties (transcribers, examiners from North-West University and interpreters).

**Data Analysis**

The interpretative phenomenological approach (IPA) was used to describe, understand and interpret the participants‘ experiences (Tuohy, Cooney, Dowling, Murphy, & Sixsmith, 2013). The IPA guidelines as described by Smith & Osborn (2007) were used. The researcher immersed herself in the transcribed data and firstly looked for possible themes. Identified themes were chronologically listed where after similar themes were clustered together. Themes from the first analysed transcript were consequently used to orientate the
subsequent analysis. A continuous process of referring back to the raw data and reformulation of subthemes followed until a final table was drawn up with five main themes and subsequent subthemes. Translated verbatim quotations from participants substantiated each theme (See appendix L).

Trustworthiness

The guidelines suggested by Lincoln and Guba (1985) were followed to ensure the trustworthiness of the research process. Dependability was ensured by accurately recording and reporting an audit trail. Credibility was maintained through making use of a flexible interview guide translated in both English and siSwati and having regular debriefing sessions with supervisors. Transferability was demonstrated through a thick and rich description of the data and the context of the participants and conformability was ensured by the process of inter-rater reliability and peer revision.

Findings and discussion

Five main themes emerged from the analyses of the data, namely:

**Theme: The influence of emotions.**

The journey of early motherhood constitutes a mixture of emotions. The Swazi adolescent mothers experienced a combination of both positive and negative emotions.

**Sub-theme: Negative emotional experiences.**

Although most of the participants were able to deal with the physical difficulties associated with pregnancy, many experienced high levels of distress during pregnancy.
The feelings and emotions of worry and stress were ignited by the unpredictability of the future and the uncertainty of what the process of motherhood would entail.

—*Eish, I think too much. ... I am stress*” (G11:248. ... 252).

—*Eish, when I was pregnant, I was worried because I didn’t know anything about a baby, what’s going on when you are pregnant, what you are going to do when the baby come out*” (G2:81).

The participants collectively expressed, clearly and without hesitance, that their pregnancies were unplanned and referred to ‘a mistake’. This finding is in line with previous research that suggests that most adolescent pregnancies were unwanted (Mkhwanazi, 2010; Richter & Mlambo, 2005) or occurred too soon (Finer & Zolna, 2011). The unpreparedness for motherhood was further highlighted by feelings of regret and self-blame and most participants indicated that they would advise other adolescent girls not to make the same mistake.

—I’m blaming myself a lot, a lot, a lot... it is my mistake... because I wish to finish my study... to have the money, to have the house... a nice home then I have the baby but now my dreams didn’t work out and I blame myself for that” (G2:405).

Shame accompanied the feeling of regret and was portrayed as follows:

—I feel ashamed. Cause now I’m not supposed to be a mother because I am too young” (G3:161).

—I’m feeling like I’m a stupid person” (G1:292).
This finding supports previous research on Swazi girls from Southern Hho-Hho region in Swaziland who experienced feelings of guilt and perceived rejection and gossip from the community (Dlamini, Van der Merwe, & Ehlers, 2003).

The girl’s heightened awareness and feelings of shame might be partly due to the fact that adolescent motherhood is against traditional Swazi culture (Van Rooyen & Hartell, 2010). All of the girls confirmed this during the interviews.

—But it does affect my culture because... everyone says that you have to, you must have a baby after marriage” (G12:376).

—Some think that if you have a baby it’s a, it’s a wrong thing” (G1:376).

In some instances the difficult emotional experiences led to feelings of helplessness and being overwhelmed. The fact that negative feelings were more prevalent during pregnancy and not so much after the baby’s birth once again indicates that adolescents were emotionally, cognitively and socially far from ready for motherhood.

—I thought some things were breaking (falling apart), really I didn’t want a child” (G10:77).

—I was think that, my future is already gone” (G11:89).

More than half of the participants experienced initial shock and disbelief in coming to terms with the pregnancy and motherhood. One participant even reported having suicidal thoughts during pregnancy; three of the nine participants considered an abortion. Research undertaken in other cultures supports this initial negative emotional experience with the confirmation of pregnancy. Sotho girls in Maseru had feelings of disbelief, confusion and disappointment when they found out they were pregnant (Lehana & Van Rhyn, 2003).
Tshivenda, Xitsonga and Sepedi speaking girls from a rural setting in South Africa reported feelings of sadness, self-blame, isolation and lack of interest (Sodi & Sodi, 2012) while the Zulu girls from a semi-rural area in Kwa-Zulu Natal verbalised feeling sad, disappointed, depressed and shocked (Parekh & De la Rey, 1997).

Many of the participants experienced feelings of anger, bitterness, heartache and isolation based on the fact that after the confirmation of pregnancy, the fathers of their children cheated on them with other girls, rejected them or weren’t emotionally supportive.

―It’s changed now, because I am having a child. While I was alone... He was loving me too much and promise me things and now, eh, he’s run away from me” (G11:308. . . 312).

―It [boyfriend rejecting her] made me feel...eish...so angry, disappointed, sad, everything and it makes me always to cry” (G3:89)

**Sub-theme: Positive emotional experiences.**

The experience of motherhood also involves positive emotions. This is a significant finding, since seven of the nine participants could recognise positive experiences that resulted from motherhood. These findings are in contrast with previous research conducted with 27 Black adolescents from Knoppieslaagte, south of Pretoria. The majority of these girls were unable to identify any positive emotions that resulted from motherhood and failed to mention the role of their children in their lives (De Visser & Le Roux, 1996).

Some of the participants pointed out the love they felt for their babies and the joy experienced by playing and spending time with them. Other participants felt proud of their babies and enjoyed the newly found companionship.
—And when you just see their faces, you just melt. . . . I love my baby” (G12:416. . . .
596).

—Ah, I enjoy to be a mother when maybe sometimes I go to shopping, I go with my
baby, some of them they like my baby ‘eh, the baby is beautiful’. And I enjoy
that” (G5:870).

Likewise, during research undertaken by Chohan (2011) adolescent mothers in Johannesburg
shared their excitement, pride, happiness and sense of fulfilment that came with having a
baby and seeing them grow.

Contrary to popular belief, adolescent motherhood can entail several positive
experiences. Based on Keyes (2002), it can be expected that the presence of positive
emotions and experience of life satisfaction contributes to the emotional well-being of the
Swazi adolescent mothers.

**Theme: Social support during early adolescent motherhood.**

All the participants experienced occurrences where family, friends, school and the
greater community were supportive as well as unsupportive or not helpful. The microsystem
thus plays a major role since experiences inevitably led to a change in social relationships in
their immediate environments. The participants’ desire and need for support were obvious
throughout the research process.

**Family support.**

The support experienced from the adolescents’ parents seemed to change over the
course of early motherhood. Initially parents were angry and disappointed, resulting in
temporary broken parent-child relationships.
"... your parent, they not support you. Like they take time to support you”

(G11:500).

—When I started changing shape, at two or four months, they didn’t talk to, to me”

(G9:333).

This initial reaction of anger and shock from the adolescents’ parents was also experienced by the Zulu adolescents from KwaZulu-Natal (Parekh & De la Rey, 1997) and Black adolescents from Knoppieslaagte in Gauteng reinforced these findings by reporting how their parents were initially upset and angry but after a while accepted the reality of their pregnant daughter (De Visser & Le Roux, 1996).

It is however not only the initial reaction of the parents to their daughter’s pregnancy that should be considered, but how this calamity of adolescent pregnancy is dealt with in the long term. From this study it seems that despite being a cultural taboo in traditional Swazi culture (Van Rooyen & Hartell, 2010), after the birth, most of the immediate family members were supportive of both the adolescent mother and her baby.

—I think, I think that I am still special to them because they love me and they show me that love that I want” (G3:69).

—They are supporting me, yes, a lot” (G5:942).

Culture.

Similarly it was found in the Zulu culture that this initial anger and disapproval of the pregnant adolescent daughter, that is often accompanied by chastising, was eventually followed by overall acceptance from the family (Preston-Whyte, Zondi, Mavundla, & Gumede, 1990). Preston-Whyte et. al. (1990) argue that the reason that repercussions of
Black adolescent pregnancies aren’t extremely harsh could be ascribed to the fact that in many African cultures children are seen as a gift from God (Akujobi, 2011). Furthermore there are minimal if any adverse effects on a girl’s marriage prospects if she falls pregnant as an adolescent. The fact that she is fertile might often make her even more desirable (Preston-Whyte et al., 1990). Previous research on Swazis also indicated that having many children is seen as a form of life insurance as children guarantee support in old age (Gule, 1994) and help maintain the political and social position of the family (Ziyane & Ehlers, 2006). It is expected that although it wasn’t explicitly mentioned by the participants in this study, that all of the above-mentioned reasons might contribute to the overall acceptance and social support given by the adolescent’s family. In the light of Keyes’s (1998;2002) model of well-being, this social acceptance and social integration can contribute to the adolescent’s well-being and ability to flourish in life.

Similar to previous research on Sesotho adolescent from Maseru (Lehana & Van Rhyn, 2003) and Tshivenda, Xitsonga and Sepedi speaking adolescent (Sodi & Sodi, 2012), the mothers of the Swazi participants were more supportive and accepting during and after the pregnancy than the fathers .

—“She [my mother] showed me everything, how a child lives, what I have to do so the child can prosper” (G3:125).

—“. . . but my father, yo, still, he’s still she run away from me. Say I disappoint” (G11:384).
Community support.

The participants experienced both judgement and acceptance from the broader community. Several of them experienced that they had lost the respect of the community, sometimes being called a bad influence on other girls.

―They don’t respect you, because you are young and you get a child.” (G11:742).

―...people you see on the street think you are a crazy girl when you meet with someone else, a girl that are not pregnant” (G2:121).

Parallel to the family's reaction, although the community was initially judgemental and insulting, they still offered support. One participant pointed out the normality of the occurrence of adolescent pregnancies in her community and two participants indicated better treatment from community members after birthing a child. It is interesting to note that four of the nine participants chose themselves to differentiate between the experience of support from the community and that of their neighbours. Not only did the neighbours accept the participants, they seemed to play a big part in advising and teaching the adolescent mothers how to take care of their babies.

―...so, my neighbour, when the baby is doing this crying...they tell me the baby is feeling the pain. When the baby is doing this, you do that, she teaches me. ”

(G2:221).

Ultimately, the Swazi community in this study showed support and acceptance of the participants. This may be linked to their inherent cultural orientation or African morality known as –Ubuntu”. This ancient African word means —humility to others” and is practised by people all over Africa. According to the 2005 January edition of the New African
magazine (as cited in Nkosi & Daniels, 2007), "Ubuntu" is built on the principles of sharing, cooperation and empathy and suggests that, "Individuals see themselves and their roles in society only in relation to the whole community to which they belong" (Mbiti, 1969, p. 108 – 109). Wissing (2006) describes black traditional South Africans as belonging to a collectivist cultural orientation with regards to their "shared patterns of behavioural readiness, assumptions, attitudes, beliefs, self-definitions, norms, values, historical background and language groupings" (Wissing, 2006, p. 60). Some research supports the idea that in a collectivist culture, people develop their self-efficacy from those around them (Earley, 1994; Pulford, Johnson, & Awaida, 2005). Furthermore Wissing and Temane (2008) propose that satisfaction with life and automatic positive expectations are associated with social support amongst collective African groups. It can therefore be argued that the social support observed in this study is firstly typical of the Swazi culture, and this experience enabled to a large extent most of the participants towards resilient overcoming.

Friends.

Only two participants maintained their friendship relationships whereas the majority experienced deterioration of original friendships. This was due to a combination of reasons; not having time to spend with friends; experiencing rejection and judgement from friends; and lack of finding common grounds with childless peers. The lack of support from existing friendships led to the need for new sources of support and as a result new friendships with other adolescent girls with children formed.

"Okay—the ladies that have no children they don’t want to stay with me cause I’m older, I am a mother. She think I’m not fitting at her age...She tell me that she will never get more—gain more—I don’t know how to explain it—she will never gain more fun things. Now that I am a mother, I will not play with them" (G2:233)
―They told me that I’m ah pregnant. They can’t be my friends anymore. They run away from me‖ (G11:332).

This finding is supported by several other studies which also suggested the negative impact of adolescent motherhood on friendships. The varying social support from friends was evident in the experiences of Zulu adolescents in KwaZulu-Natal. Although some friends were encouraging, others preferred not to associate with them (Parekh & De la Rey, 1997). The Sesotho girls from Maseru (Lehana & Van Rhyn, 2003) perceived the loss of peer support as creating a stressful environment and the Swazi girls (in Swaziland) felt alienated, not accepted by their peers and neither fitting in with the older women (Dlamini et al., 2003). The loss of friendships and peer support are of concern especially considering that participants are in the adolescent phase of their lives where peer relationships are pivotal (Collins, 2008; Sigelman & Rider, 2011). In the light of Erikson’s theory of adolescent development (Saddock & Saddock, 2003), it can be expected that lack of support from peers greatly affects the process of identity formation.

School.

Although schools in South Africa are obliged to support adolescents who become mothers, it is unfortunately not always the case (Bhana, Morrell, Shefer, & Ngabaza, 2010). Some participants experienced encouragement from teachers to continue schooling. Others were chased away, being told that a mother’s place is at home with her baby.

Father of the child.

The participants were very aware of the inability of the biological fathers to offer financial support since most were still at school or without jobs. Moreover, they offered neither emotional nor social support, and denied duties towards child rearing.
Only two participants indicated that they were still in a stable relationship with the child’s father, who also supported and helped the participant. The remaining participants indicated that their relationship with the child’s father was either complicated as he was unfaithful or that the relationship had been terminated. The majority of the fathers had minimal involvement with their children. Some participants however indicated that the broken relationship with the biological fathers didn’t affect them seriously, as their focus has shifted to positive relations with their babies.

“Ah, it’s changed now when the baby is coming, decide to cheat with other girls and if I told him, didn’t listen for me. So ah, I don’t have a problem about that, the thing that I want, I just want to take care for my baby, grow up, after that I will quit for him. Look someone that he will, he will take for me or be serious with me” (G5:774).

**Theme: Challenges experienced during early motherhood.**

Swazi participants experienced early motherhood as posing several challenges. The adolescent life phase is hurried and the teenager is forced to adapt to the life phase of a mother (Sadler & Cowlin, 2003). True to previous research across different cultural groups and various socio-economical classes in South Africa, the most prominent challenge experienced was the significant lifestyle changes that occurred when becoming a mother (De Visser & Le Roux, 1996; Parekh & De la Rey, 1997; Sodi & Sodi, 2012). One of these lifestyle changes included the interruption in education (Grant & Hallman, 2006; Kaufman et al., 2001; Sodi&Sodi, 2012). Participants missed out on school around the birth of the baby and at the time of the interviews only four of the nine girls had returned to school, although most expressed the desire to further their education. Two participants that had returned to school voiced the constant internal conflict experienced by being torn between wanting to be
with their babies but at the same time wanting to be at school and having ambition to further their education.

—Sometimes I find it difficult, because I have to go to school...look after my baby and sometimes...they will need us at school, even Sunday. I don’t get time to see him, and...do things with my little boy, so I will say —heylife is too difficult, now I want to go home and just spend time with him”, but sometimes, but the other way around, I say —at the end of the day I want to be something” and I have to be at school. So these two things just come and go . . . . Ja, because I want two things at the same time” (G12:404 . . . . 408).

The participants’ life styles were further interrupted by the realisation of the several needs that a baby has and attending to responsibilities (e.g., washing, feeding, playing, cooking and clothing for the baby). These added responsibilities were not necessarily part of their prior life phase as adolescents. Three participants mourned the loss of leisure time and G3 specifically felt that she was losing out on being young.

—I played soccer, ladies football, but now because I have a baby I don’t have that much time to go and play—Now I don’t have the time to do lot of things” (G2:297).

—Cause I’m still young. I want to play with my friends, walk with them. Now I have a baby. I have to live at home, stay with him” (G3:266).

Not only is leisure time forfeited but also school assignments and homework get neglected. Participants were faced with the hard reality of how time-consuming a baby can be.
Sometimes, I could find that I have some work to do, but because I have a baby I have to let stop this side and make sure that I spend the time with my baby... maybe I’ll wake up at night and do what I have to do. If he’s sees that I am awake she also wakes up... so have to leave this one and I look after him.” (G12:281).

African girls from KwaZulu-Natal also found the double demands of schooling and motherhood hard. They reported feeling tired and had difficulty handing in school assignments on time (Bhana & Mcambi, 2013).

Along with lifestyle changes, participants experienced the burden and responsibilities of ‘being a provider’. The majority of the participants had financial constraints, even more so when having to raise a child. Not only were they concerned about the present financial situation but also about future possibilities of looking after their children due to being unemployed. Most relied on their families for financial support, only two had support from the father of the child’s family. One participant, being parentless, received support from a Christian feeding scheme. The adolescent mothers’ dependency on their families infringes on normal adolescent development that aims for a feeling of independency (Collins, 2008) and might be why some participants experienced the inability to financially look after their children as a painful process. Some participants also indicated how guilty they felt being dependent on their parents and how it often caused fights between them.

“You have to think for the child and it takes your money. Even if you get a little money and want to buy yourself something, you realise that you have to think of the child first and the money is only a little. If you find there is no food, it needs me to buy food” (G10:229).
—‘It’s very annoying that I can’t care for my child. That I don’t have the money as a mother’”(G9:467).

Another challenge experienced was the helplessness when their babies got sick and not knowing what to do and when to take them to the clinic.

—‘It’s affecting me, that, when the baby is sicking.’” (G5:1056).

The challenges experienced by the participants corroborates existing literature and the many sacrifices and compromises that the adolescent must make (Kaufman et al., 2001). Adolescent mothers are often concerned about their children’s health and unsure whether they should stay at home with their ill child and miss school (Chohan, 2011). Adolescent mothers often added to their families’ financial burden (De Visser & Le Roux, 1996; Spear, 2004) and economic hardship. These difficulties added to uncertainty about their future financial status which often caused great distress (Dlamini et al., 2003).

Theme: Personal growth.

The experience of adolescent motherhood was accompanied by personal growth, evident in subsequent sub-themes:

Sub-theme: Self-acceptance.

Some participants had an awareness of their personal immaturity and limitations. These participants accepted their blunders, and were able to admit that they had made a mistake. They could voice the difficulty of being a mother, therefore acknowledging the need for help. In light of their adolescent phase of development, this can be considered as a mature way of dealing with their situation.
Sub-theme: Increased ambition after becoming a mother.

It was evident that the new responsibilities accompanied by motherhood led to an increased ambition to further their education. In keeping with the findings there seemed to be a realisation of the importance of education and the impact thereof (Chohan, 2011). The participants further developed a future perspective after becoming mothers and became aware of not only immediate needs, but also of what would be required in future with regards to children’s needs.

—Ah, I don’t care about that. Now I am focused on learning. I learn even at night, I don’t go out. The sun goes down, but I’m inside looking at my books. If the child is sleeping, I am getting more clever learning my books. so that I can gain something at school, so I can finish grade 12” (G10:185).

—..by the time I was living alone at home, I was just thinking that if I cook now, tomorrow I’m not cooking. I never cared about something else; I just cared about what is happening now, about the next thing...now I am a mother I know I have to look forward to my child’s future, I know that I have a bright future ahead me and I have to study to do that, but if I was not a mother I think I will not going to think all these things” (G1:387).

Some participants experienced a change in their priorities; what used to be important before was not as important anymore, resulting in willingly giving up going out with friends, spending time with boys and going to parties.

—Now, I realise I am a mother of a child. I don’t go to the guys anymore. I used to go, thinking it’s nice. Now, I don’t want to, I feel like a mother of a child” (G10:201).
Sub-theme: Responsible decision making after birth of the baby.

Several of the participants displayed risky sexual behaviour before becoming pregnant. Apart from being sexually active as an adolescent and outside of wedlock, they didn’t use any contraceptives, or used contraceptives ineffectively and irregularly. Responsible decision making with regards to sexual matters compares favourably with previous research which suggests that adolescents in South Africa effectively start using contraceptives only after having their first child (Kaufman et al., 2001). The experience of early motherhood further brought about certain insight as to life matters and responsible choices:

—I learn that I have to learn hard, I don’t have to do the same mistake. I’ve learned that this was a mistake, that if I can give birth or get pregnant to the second baby it’s not a mistake. A mistake happens once.” (G1:391).

Sub-theme: Character development and gained strengths as a result of having a baby.

Motherhood proved to be a learning process for many of the participants, since several participants experienced character development and a positive change within themselves. Some participants developed a sense of altruism and considered their babies’ welfare more important than their personal needs:

—Mmm, it changed me a lot, because I could remember if I had money I will spend it the way I like, but now even if I have maybe that hundred rands, all I, one thing comes in my mind, my baby . . . . I don’t even think about myself, I think about my baby, my baby” (G12:384 . . . . 388.)
—Ah, the babies making a different, because if I was not having the baby, I was not going to think things like this.” (G1:372).

Another positive experience of motherhood that arose from the interviews was the fact that the participants gained better knowledge on how to raise children. Two participants explicitly mentioned that part of their positive experience was that after having their own baby, they developed a compassion for all children that crossed their paths.

—I have that ticket to take care of another child you see. I will never see the child crying and continue and leave the child crying. I will take care and say why are you crying? And when the child or someone else is suffering, I feel the pain cause now I have my own child. When someone beats the child, I feel the pain, cause I am a mother now. I know the pain, the pain when the baby come out, I know it. I know the pain, so I take the baby and I say: Why are you crying and I hold it so. Now that I am a mother, I need to take care another child, not my child only.” (G2:317).

Personal growth experienced by the participants affirms findings from a study on adolescent mothers from a public school in Johannesburg. In keeping with the findings, these girls felt that motherhood contributed to personal growth and maturity and enhanced their sense of responsibility and determination in achieving career goals (Chohan, 2011). Similarly a phenomenological study conducted in England suggested that although the adolescent mothers also had to face difficult circumstances, having a child changed them and enabled them towards greater personal strengths. Motherhood encouraged them to become more driven in life, considering a career and finishing education in order to look after their children (Seamark & Lings, 2004). Rolfe (2008) further suggests that motherhood allowed adolescent girls to become active and instigate positive change in their lives.
Theme: Resilience.

Resilience signifies patterns and processes of positive adaptation in the midst of significant risk (Masten & Wright, 2010; Obrist, Pfeiffer, & Henley, 2010). It is evident in the following statements that the participants experienced motherhood as a difficult process:

— "I suffer. Now I have a baby, you don’t know how much challenges I have” (G2:377).

— "To be a mother is very difficult. To take care of a family and to raise a child you also show to other mothers what it is and you have to be strong to be a mother and you have to fight the mother’s fight. You see?” (G9:451).

Similar to previous research (Chohan, 2011; Clifford & Brykczynski, 1999; Spear, 2004), some participants in this study demonstrated the ability to rise above challenges posed by adolescent motherhood. They took ownership of their problems, facing their responsibilities as well as effectively coping with motherhood by exhibiting loving care for their children.

Effective coping manifested in several ways: Six of the nine participants appeared to have taken ownership of motherhood and taking care of their babies and expressed this as acknowledging the innocence of the baby, taking responsibility for their baby, testifying to positive motherhood experiences, and, exercising a pragmatic attitude towards adolescent motherhood. This confirms Seamark and Lings's finding (2004) that adolescent motherhood does not destroy all future hopes and plans. Furthermore, although the participants acknowledged falling pregnant at such a young age as a blunder, it seemed that they were determined not to give up their babies, but rather to persevere in spite of difficult challenges.
―Even if her father ran away or did what, but you develop that love and say this is mine no matter what‖ (G12:424).

―I’m still fine, because I got used to it. I don’t have problems now because I could never throw the child away‖ (G10:173).

―In the end I accepted that I am a mother‖ (G9:321).

These participants had their baby’s best interest at heart and expressed the desire to be good mothers:

―They even say ―wow, just a minute you don’t even forget about your baby?‖ and I said no. Even if, how, I don’t care if the money is small, but when I just hold it with my hands I think of my baby wants this‖ (G12:388).

―I wish to be a great mother to my child. I wish her to be a good girl and I wish to be successes like other mothers—and I don’t want my baby to live the way I live, the way I grow. I grow hard, so now I will take care looking after my baby so now I am a mother‖ (G2:89).

These findings support previous research, that rejects the prevailing belief that adolescent mothers are irresponsible, immature and lack the skills to look after their children. Adolescent mothers do have the capacity and desire to be good mothers (Chohan, 2011). Seamark and Lings (2004) found that adolescent mothers were proud of their children and wanted what was best for them. For some mothers this meant caring in ways they had not experienced whilst growing up.

These participants’ high levels of resilience might be attributed to their specific culture. Previous research debates that African families are often subjected to a lack of
material resources, hardships and underdevelopment, yet they often possess the miraculous ability to overcome setbacks and "make something from nothing" (Moser, 1998:5).

**Negative experiences of adolescent motherhood.**

There were however, three participants that seemed not to be coping with their role as mothers and experienced lower levels of well-being. These participants experienced early motherhood as mostly problematic; they had difficulty in taking ownership of being an adolescent mother and the reality of having a baby. Participant G1, an orphan herself, recently decided to put her child in temporary foster care with a Christian support group. She attempted abortion and felt inadequate to look after her child. She even goes as far as to say that she doesn’t love her baby.

— . . but when I’m just holding my baby I have bad memories. I don’t see a reason of being a good mother. Because I wish lot of things to do it to my baby, but I can’t. That’s the problem, maybe, aha, I don’t know. I don’t see a thing of being a good mother, because I’m not the person that I wanted to be” (G1:411).

— It’s being a mother who’s not caring, who does not love the baby” (G1:427).

These mostly negative experiences of early motherhood were associated with specific issues, such as increased feelings of bitterness towards the father of child, and the loss of childhood. Although participant G3 enjoyed playing with her child, she did not experience motherhood as positive despite the fact that she indicated support from family and friends. These experiences were put into words in the following way:

— He goes out to have fun. It make my heart feel pain, I stay alone at home all the time (G3:218).
—*I was thinking about it was going to be nice when I have a baby but now I see that it is not nice because I am too young*” (G3:25).

—*To be a mother is very difficult in these times because things have now gone out of my reach*” (G3:358).

One participant repeatedly indicated that there wasn’t anything good about being a mother. She experienced rejection from her father, judgement from the community and no support from her boyfriend or friends.

—*To become a mother, like me I can say no, I don’t like to be a mother, but I am a mother because I am having a child. . . . . There isn’t a positive thing*” (G11:420 . . . . 424).

It is interesting to note that at the time of the interviews only four of the nine participants had returned to school. Three of these four participants were perceived as not being resilient and not coping well with motherhood. It can therefore be hypothesized that simultaneously being a mother and a scholar is a major challenge and this finding echoes the dire need for support programmes in South Africa to assist these adolescent mothers in the early stages of motherhood.

**Conclusion**

The article explored adolescent motherhood (pregnancy included) amongst Swazi girls. The five main themes identified pertained to the influence of emotions; social support during early adolescent motherhood; challenges experienced during early motherhood; personal growth; and resilience. It is evident that the participants had both negative and positive emotional experiences. Negative emotions were more prevalent *during pregnancy*
whereas the positive emotions after the birth of the baby contributed to the well-being of the adolescent mother. All the participants experienced incidences in which their immediate environment (family, friends, community, neighbours, school, and boyfriends) rejected them and were unsupportive due to their newly found status of motherhood. This was especially evident in the ongoing lack of support offered by the biological father of the baby and the deterioration of original friendships. However, it became apparent that the inherent Swazi culture and African principle of ‘Ubuntu’ resulted in overall acceptance and support.

Most participants experienced personal growth and a sense of maturity. Insight gained from motherhood resulted in participants making more responsible choices with regards to the use of contraceptives, changing their priorities, positive character development, and becoming more ambitious and future orientated. The personal growth of most participants was clearly indicated by the mastering of several challenges related to early motherhood.

Early motherhood entailed several challenges of which a change in lifestyle was the most significant. Other challenges included: the responsibilities of being a provider, financial constraints in present and future, interrupted education, loss of leisure time and increased vulnerability and the experience of helplessness.

Despite the fact that adolescent motherhood was experienced as difficult, most participants demonstrated high levels of resilience, portraying effective coping strategies by taking responsibility and ownership of their babies and expressing the desire to be good mothers. Considering the findings and verification of previously discussed themes, it can be assumed that the prevalence of protective factors contributed to the resilience of these participants. The following protective factors enhanced their strength and motivation to cope with adversities and to re-establish normal life: existential support in the form of cultural
traditions (Masten & Wright, 2010) that ultimately led to social integration (Keyes, 1998); the social support experienced by family and the greater community (Van den Berg et al., 2013); experiencing positive emotions (Van Schalkwyk & Wissing, 2010); and experiencing personal growth and self-acceptance (Keyes, 2005; Ryff & Keyes, 1995).

It can therefore be concluded that despite the fact that adolescent mothers are faced with crises related to the life stage of adolescence as well as the demands of motherhood (Sadler & Cowlin, 2003), some adolescent mothers are capable to re-direct from their own developmental tasks and coping to Erikson's stage of generativity (Hurlbut, Culp, Jambunathan, & Butler, 1997).

**Limitations of this study**

Due to the phenomenological nature of the study and the sample-size, the results cannot be generalised to all populations and therefore further research on the experience of adolescent motherhood will be necessary. Some participants had difficulty putting their experiences into words possibly as a result of the language barrier and/or the life stage that they are at. It is therefore a limitation that a pilot study was not undertaken prior to the data collection as it could have assisted the researcher in formulating more appropriate, age-and culture-specific questions. Subsequently the researcher could have identified the necessity of making use of triangulation by using pictures or making collages to express emotions or ideas. If financial resources were available the presence of an independent interpreter would have been beneficial to make interviews more information-rich. Alternatively if the researcher was fluent in siSwati, it would have allowed for more accurate follow-up questions in the cases where participants switched over from English to siSwati.
Recommendations

Recommendations to enhance the well-being of Swazi adolescent mothers include the following: Health practitioners at clinics and hospitals should offer external emotional and social support in the form of support groups. Support groups should educate and empower adolescent mothers to deal with pre- and post-natal challenges by addressing (e.g., information on pregnancy, time management skills, basic knowledge on child rearing, developmental milestones and activities, childhood diseases, conflict managing skills, financial management, and emotional awareness). Support groups further provide a platform for talking about positive experiences of motherhood, therefore improving well-being and resilience (Folkman & Moskowitz, 2000; Fredrickson, 2013) and can potentially give rise to the formation of new friendship with fellow-adolescent mothers.

The role of schools is very important in being able to empower the adolescent mothers towards academic and life success. The challenges of teenage pregnancies and early motherhood offer valuable opportunities for improved well-being, resulting in post-traumatic growth and resilience (Schaefer et al., 2013). In the light of these findings it is recommended that mutual-aid support groups or clubs at schools should be established with the assistance of NGOs, universities or allied medical staff. These clubs could facilitate the numerous needs and difficulties experienced by the adolescent mothers, such as honest coping with negative emotions, motherhood and achieving their dreams. Schools should further be encouraged to allow for pregnancy prevention programs.

Recommendations for future research entail: Follow-up studies two or three years into motherhood to investigate whether the participants adapted successfully to motherhood; exploring the benefits of support programs; exploring the experiences of caregivers/familial support of the adolescent girls so that appropriate guidelines can be given to assist caregivers
to support, care for and empower the adolescents during motherhood; describing the experiences and perceptions of the father of the child in order to clarify the reasons for their absence in some instances; further investigating the psychological well-being of Swazi adolescent mothers by using established well-being scales. Lastly, if similar research is conducted amongst other cultural groups, a pilot study should first be conducted.

Concluding remarks

The researcher set out to explore and describe the experiences of early motherhood amongst Swazi adolescents. Existing literature often over-emphasises negative accounts of adolescent motherhood shifting focus away from the positive experiences of adolescent motherhood and the role that a specific culture can play in coping with adolescent motherhood. By approaching this research through a lens of positive psychology both the positive and negative experiences of early motherhood were highlighted. Problems or difficulties that adolescent mothers experienced were acknowledged (Peterson, 2009), whilst embracing well-being. The rich information gathered provide guidelines for future pregnancy prevention programs as well as suggestions on how to compile a support program for assisting adolescent mothers to become more resilient as living examples of flourishing persons.

Section C

Integrated summary of the study, conclusions and recommendations

The purpose of this section is to give a brief overview of the problem statement and a summary of the main findings in order to adequately answer the aim set for this study. The researcher further discusses the findings and conclusions of the study and gives recommendations which are based on the research results. A discussion of the strengths and limitations of the study and possible future research opportunities will also be presented.

Overview of the research topic and problem statement

The prevalence of adolescent pregnancies and motherhood amongst Swazi adolescents in South Africa was identified as the problem that guided this research. Little information was available on Swazi adolescents’ subjective or personal experiences of early adolescent motherhood. It was evident that international research focused mainly on the negative stigmas attached to adolescent motherhood. The researcher was aware of the dangers for possible prejudices as to this specific cultural group in dealing with difficult life challenges. The question arose as to what and how do Swazi adolescents experience early motherhood?

Summary of findings

The research findings indicate that early motherhood amongst Swazi adolescents comprises both positive and negative experiences. This was expressed by the participants as dealing with good and bad or negative emotional experiences during the course of early motherhood. All the participants experienced incidences in which their immediate environment (family, friends, community, neighbours, school, and boyfriends) rejected them
and were unsupportive. This was especially evident in the ongoing lack of support offered by the biological father of the baby and the deterioration of original friendships. Ultimately however, it became apparent that the inherent Swazi culture and African principle of "Ubuntu" resulted in their being mostly accepted and supported. This finding once again highlights the importance of culture specific studies.

Furthermore, most participants experienced personal growth and a sense of maturity. Insights gained from motherhood resulted in participants making more responsible choices with regards to sexual behaviour, for example the use of contraceptives, changes as to their priorities, developing their characters, becoming more ambitious to achieve their personal life goals and becoming future orientated. The personal growth of most participants was clearly indicated by the mastering of several challenges related to early motherhood. A change in lifestyle was the most significant problem to overcome, and other challenges included the "burden" of being a provider, financial constraints in present and future, interrupted education, loss of leisure time, and, the experience of helplessness in times of need (e.g., when the baby is ill).

Despite the fact that adolescent motherhood was experienced as a difficult occurrence, most participants (six of the nine) demonstrated high levels of resilience. These participants demonstrated effective coping strategies by taking responsibility and ownership of the difficulties associated with adolescent motherhood, and expressed the desire to be good mothers.
Personal reflection on the research

The researcher witnessed personal growth within herself during the process of completing her thesis. Initially when the research started, the focus was more on exploring and describing the experiences of early Swazi adolescent motherhood in order to provide possible guidelines for pregnancy prevention programmes. During the course of the research process, the researcher developed a deeper understanding of the influence and essence of motherhood as she herself became a mother. Even with several protective factors in place, like family support, positive experiences and knowledge on child development, the early stages of motherhood had challenges and required the presence of a strong emotional, psychological and social well-being. One of the biggest challenges was balancing the roles of student, occupational therapist, wife and mother. The researcher's own levels of resilience were challenged daily. This personal experience combined with the research findings emphasized the dire need of supporting adolescent mothers and ensuring their well-being.

Having had this first-hand experience of motherhood, the researcher felt a sense of awe and admiration for participants who managed to cope effectively with unplanned adolescent motherhood and to overcome the many adversities. On the other hand, investigating and learning about the difficulties that some of these girls had to endure, the researcher developed a new-found understanding and empathy for the participants who couldn't cope effectively with adolescent motherhood. The researcher furthermore gained respect for the African approach of “Ubuntu” and believes there is much to learn from Swazis with regards to acceptance and the social support offered to one another. If anything else, the findings and the experience of this research process further ignited the researcher's passion to support adolescent mothers as to the enduring challenges concerning the process of motherhood.
Discussion

Conclusions of the study

Most of the findings supported previous research on adolescent motherhood as experienced in diverse cultural groups. The findings of this study contribute to the existing literature on Swazi adolescents’ experience of motherhood, a research area that is lacking in South Africa.

Findings that can be seen as fresh gems are: (a) Swazi adolescents in the Nkomazi district in South Africa who participated in this study experienced motherhood as both negative and positive. This finding is in contrast with the popular belief that adolescent motherhood is mostly associated with negative experiences and results in mostly negative outcomes as argued by several researchers (Dlamini, Van der Merwe, & Ehlers, 2003; Kaufman, De Wet, & Stadler, 2001; Panday, Makiwane, Ranchod, & Letsoalo, 2009; Richter & Mlambo, 2005). Not only did the participants testify to positive motherhood experiences, but the process of motherhood also had positive outcomes such as personal growth, experiencing positive emotions and the development of higher levels of resilience;

(b) Furthermore, negative emotions (bitterness, shame, shock, anger, regret, stress, helplessness) were more prevalent during pregnancy, whereas the positive emotions (feeling proud, experiencing joy, love, acceptance and companionship) were mainly experienced after the birth of the baby. The experience of positivity, where negative emotions were outnumbered by positive emotions, contributed to the well-being of the adolescent mother;

(c) The majority of the participants showed resilience in dealing with the challenges of motherhood. Considering the findings of previously discussed themes, it can be assumed that the prevalence of protective factors might have contributed to the participants’ increased
levels of resilience. The following protective factors contributed to the enhancement of their strengths and motivation to cope effectively with adversities: existential support in the form of cultural traditions (Masten & Wright, 2010) that ultimately led to social integration (Keyes, 1998); the social support experienced by family and the greater community (Van den Berg et al., 2013); experiencing positive emotions (Van Schalkwyk & Wissing, 2010); experiencing personal growth and self-acceptance (Keyes, 2005; Ryff & Keyes, 1995).

Therefore, it can be concluded that despite the fact that adolescent mothers are faced with different life stages simultaneously (Sadler & Cowlin, 2003) some are capable to re-direct from their own developmental tasks and coping towards Erikson’s stage of generativity (Hurlbut, Culp, Jambunathan, & Butler, 1997); and

(d) Also, it was interesting to note that at the time of the interviews only four of the nine participants returned to school. Three of these four participants were perceived as not being resilient and not coping well with early motherhood. It can therefore be hypothesized that simultaneously being a mother and a scholar is a major challenge and this finding echoes the dire need for support programs in South Africa to assist these adolescent mothers in the early stages of motherhood.

Other findings that arose that were not necessarily prominent, but that are worth mentioning is the fact that all the participants had knowledge about their cultural beliefs and the fact that adolescent pregnancies were prohibited in their culture (Van Rooyen & Hartell, 2010), but still they did not adhere to these “rules”. Some of the participants blamed this on being an adolescent, “unstopable hormones” and the need for independence as to make their own mistakes.
Previous literature on Swazi adolescents from the Southern Hho-Hho district in Swaziland indicated that motherhood could be seen as a process of gaining adult status (Dlamini et al., 2003), but in this study only two participants felt as if the community treated them with more respect after the birth of their babies. Additionally, unlike the general belief that in the Swazi culture having a boy child is more favourable because it secures the family name (Ziyane & Ehlers, 2006), not one of the participants referred to the importance of the gender of the baby or the effect it had on the support experienced by their families.

Similar to previous research on adolescent girls in Limpopo (Maputle, 2006), the pregnancy symptoms experienced by the participants were not different from normal pregnancy symptoms amongst other aged women and included nausea, tiredness which was described as "la ziness" by many girls, and one participant mentioned mood swings. The participants' inability to give detailed descriptions of how they had experienced their pregnancy and the birth process is noteworthy. The participants gave vague answers as to their experience of the birth process, or the question was just ignored. Mercer (1985) substantiates this point that teenagers are less likely to describe physical and emotional symptoms comprehensively or identify complications during birth. Likewise most Swazi girls from the Southern Hho-Hho region in Swaziland failed to recognise the signs and symptoms of pregnancy (Dlamini et al., 2003). This is an important finding which indicates the adolescents' lack of information about their physical health, pregnancy and positive human health.
Strengths and implications of the research

The researcher set out to explore and describe the experiences of early motherhood amongst a group of Swazi adolescents. The rich information gathered on both positive and negative experiences of Swazi adolescent motherhood provides guidelines for future pregnancy prevention programs as well as suggestions on how to compile a support program for assisting adolescent mothers to become more resilient. The application of the research findings could encourage health professionals and educators to share the experiences of Swazi adolescent mothers and implement support programs at schools and clinics.

This research echoed international research findings on early adolescent motherhood, but has also created opportunities for further research of other cultural groups in the South African context. While the importance of person-in-context was highlighted, this study has set the groundwork for further studies focusing on the well-being of adolescent mothers versus the mere addressing of possible risk factors. As such, this research furthermore contributed to the existing body of academic literature on the topic of adolescent motherhood and added to the archive of research on the Swazi culture.

A further positive outcome of the research process was that for some of the adolescent mothers the ability to share personal experiences of a challenging time in their lives was possibly a cathartic moment. They had the opportunity to share and reflect on both the good and the bad experiences in a safe environment, free from judgement. This in itself might have contributed to their emotional well-being.
Limitations of the research

A phenomenological study approach was utilized as it provides rich insight and discussion around the experience of motherhood. This does, however, implicate that the results of the study cannot be generalised to all populations. Also, it must be stated that further research about the experiences of early motherhood for Swazi adolescent mothers on a larger scale will be necessary.

Due to time and financial constraints, the researcher was forced to meet participants, explain the purpose of the research and interview a participant on the same day. The researcher is of the opinion that if circumstances allowed it, it would have been better to schedule a pre-interview on a separate day to introduce herself to a participant in order to allow more time to consider participation in the study. This would also have allowed the researcher and participant to feel more at ease with one another, and could have made the participants even more comfortable on the day of the interview when having to answer personal questions on the experience of early motherhood. This initial interaction might also have given the researcher adequate time to consider whether the participants’ English was good enough to participate in this specific study.

Interviews could have been more accurate and information-rich if the researcher was fluent in siSwati. In addition, if financial resources for an independent interpreter to be present were available it would have been preferable, allowing the researcher to ask more accurate follow-up questions in cases where participants switched over from English to siSwati.

This leads to the next limitation: The researcher was under the impression that an adolescent with English as second language would be able to express herself thoroughly.
Although caution was taken to formulate culture and age-appropriate questions by consulting Swazi health professionals working with Swazi adolescents, some of the questions were still difficult to comprehend even if rephrased in easier language. It is therefore a limitation that a pilot study was not undertaken before the actual research took place.

A pilot study would have further assisted the researcher in realising that she sometimes reverted back to closed ended questions when the participants struggled to express themselves and didn't allow enough time for participants to struggle through a question. Fortunately the researcher realised this early in the study and a significant difference can be seen in the style of questioning during the initial interviews and later interviews.

Some of the participants had difficulty putting their experiences into words, possibly as a result of the language barrier, and/or due to the life stage that they are at, and/or due to the fact that expressing personal feelings and experiences was not learned in this particular culture. To overcome this, the researcher could have made use of triangulation by means of using more than one way of data collection. Perhaps by making use of more visual cues like drawings or pictures in order to express an emotion or allowing participants to make a collage from magazine pictures to portray and reflect upon experiences could have worked more effectively.
Recommendations

Recommendations for health workers.

Early adolescent motherhood constitutes a mixture of positive and negative emotions. The experience of mainly negative emotions during pregnancy was associated with their initial reaction due to the lack of support experienced from their immediate environment in specifically the Swazi culture. It is therefore of key importance for health practitioners at clinics and hospitals to intentionally offer emotional and social support not only during pregnancy, but also after the birth of the baby. This can be done in the form of support or mutual-aid groups.

Support groups should first of all offer adolescent mothers opportunities to talk about their personal experiences and their pregnancies, seeing that for most participants the biological fathers of the babies –disappeared”. Also, since the initial disappointment of the adolescent mother and her immediate family must be dealt with, these one-on-one encounters or support groups could offer valuable opportunities towards effective coping and the building of resilience. Providing important information about pregnancy including physical changes, possible emotional challenges and the labour process is strongly suggested. Adolescents should also be prepared for the possible challenges that might arise during early motherhood. Follow-up post-natal support groups should address some of the challenges that arose during the interview, and empower the adolescent mothers on how to deal with these difficulties.
The following suggestions are taken from the findings, for topics to address during these support groups:

- Assisting mothers with time management skills and how to work out a daily schedule.
- Empowering mothers with information about a healthy lifestyle during and after pregnancy.
- Enhancing emotional awareness and emotional expression.
- Teaching basic child rearing skills.
- Assisting mothers with knowledge on the basic developmental milestones of the child and providing them with stimulation activities that they can do with their child.
- Sharing information on typical childhood diseases and identifying when to take the child to the doctor.
- Practicing constructive conflict managing skills.
- Giving guidelines for basic budgeting and financial management.

The researcher recommends that adolescent mothers should also be provided with ample opportunity to rejoice in the positive experiences of motherhood and be given a chance to express the joy and awe, namely their positive emotions associated with motherhood. The deliberate use of positive emotions can promote their personal well-being as well as enhance their efforts aimed at resilient overcoming (Folkman & Moskowitz, 2000; Fredrickson, 2013). These support groups can also potentially fulfil the need of the participants to develop new friendships with other adolescent mothers.

**Recommendations for schools.**

The role of schools is very important as enabling communities to empower the adolescent mothers towards school and life success. The challenges of teenage pregnancies
and early motherhood offer valuable opportunities for improved well-being, resulting in post-traumatic growth and resilience (Schaefer et al., 2013).

In the light of these findings it is recommended that mutual-aid (support) groups or clubs at schools should be established with the assistance of NGOs, universities or allied medical staff. These clubs could facilitate the numerous needs and difficulties experienced by the adolescent mothers, such as honest coping with negative emotions, dealing with personal disappointment, low levels of self-acceptance, as well as motherhood as a stepping stone to achieve one’s dreams. Schools should further be encouraged to allow for clubs focusing on healthy relating and responsible choices as to sexual activity, and pregnancy prevention programs.

**Recommendations for future research.**

First of all it is recommended that in future research amongst other cultural groups, the researcher should first conduct a pilot study in order to determine the most suitable interview questions, determine the cultural differences and to bridge any possible language gaps that might exist. Another suggestion is to make use of more than one research technique or strategy to collect data (e.g, making a collage or choosing from pictures in order to allow participants to express their thoughts and feelings in more detail).

A follow-up study two or three years into motherhood would be beneficial to investigate whether the participants adapted successfully to early motherhood or not. Another suggestion would be to implement a support program for the participants and to conduct research on the impact of external support on the overall well-being of these adolescent mothers.
Seeing that current and previous research highlighted the importance of family support, it would be interesting to do a phenomenological study about the caregivers' experiences of the adolescent mothers. Such research could be used to provide guidelines on how to empower caregivers to efficiently support adolescents during motherhood.

Also, since South Africa is a country identified with a high occurrence of Fetal Alcohol Spectrum Disorder (FASD), the use of alcohol and/or substances during pregnancy by adolescent mothers should be looked at. Seeing that the use of alcohol or binge drinking during the first three months of pregnancy could present serious implications for the development of the foetus as to, for example brain damage, future research could examine the use of alcohol and risky sexual behaviour among the various South African cultures (National Drug Master Plan, 2012–2016).

Another suggestion for research would be to explore experiences and perceptions of the father of the child in order to have a realistic viewpoint on what they are going through and to clarify the reasons for their absence in some instances. Findings could be used to empower the fathers to be part of their children’s lives.

The researcher is of the opinion that the psychological, emotional and social well-being of Swazi adolescent mothers should be further examined. This could be done by utilising standardised scales of well-being. This information could be used to establish what facets of their well-being could be deliberately enhanced towards higher levels of positive functioning, resilient overcoming and sustainable well-being.
Final comments

Although each individual’s experience of early motherhood is unique, the researcher was able to identify shared experiences amongst the Swazi participants and adolescent mothers from other South African cultures. Early adolescent motherhood constituted both negative and positive experiences which helped shaped the participants in this study. It can be concluded that adolescents from all cultures should be encouraged by this research to speak more openly, honestly and frequently about their experiences, their challenges and their need for support. This research study will hopefully voice the experiences of adolescent mothers, potentially prevent adolescent pregnancies, assist in supporting adolescent mothers, guide further research and ultimately add to the well-being of adolescent mothers.

Appendices

Appendix A: Instructions to authors

Intended Journal: Journal of Psychology in Africa

The manuscript has been styled according to the mentioned journal’s specifications. The format, style and ethical guidelines, provided by the Publication Manual (6th ed.) of the American Psychological Association (APA 6), were followed.

Editorial policy

Submission of a manuscript implies that the material has not previously been published, nor is it being considered for publication elsewhere. Submission of a manuscript will be taken to imply transfer of copyright of the material to the publishers, Taylor and Francis. Contributions are accepted on the understanding that the authors have the authority for publication. Material accepted for publication in this journal may not be reprinted or published without due copyright permissions. The Journal has a policy of anonymous peer review. Papers will be scrutinised and commented on by at least two independent expert referees or consulting editors as well as by an editor. The Editor reserves the right to revise the final draft of the manuscript to conform to editorial requirements.

Publishing Ethics

By submitting to JPA for publication review, the author(s) agree to any originality checks during the peer review and production processes. A manuscript is accepted for publication review on the understanding that it contains nothing that is abusive, defamatory, fraudulent, illegal, libellous, or obscene. During manuscript submission, authors should declare any competing and/or relevant financial interest which might be potential sources of bias or constitute conflict of interest. The submitting author must provide contact information.
for all co-authors. The author who submits the manuscript accepts responsibility for notifying all co-authors and must provide contact information on the co-authors.

The Editor-in-Chief and Associate Editors will collaborate with Taylor and Francis using the guidelines of the Committee on Publication Ethics [http://publicationethics.org] in cases of allegations of research errors; authorship complaints; multiple or concurrent (simultaneous) submission; plagiarism complaints; research results misappropriation; reviewer bias; and undisclosed conflicts of interest.

**Manuscripts**

Manuscripts should be submitted in English. The manuscripts should be typewritten and double-spaced, with wide margins, using one side of the page only. Manuscripts should conform to the publication guidelines of the latest edition of the American Psychological Association (APA) publication manual of instructions for authors.

**Submission**

Manuscripts should be submitted to the Editor-in-Chief, Journal of Psychology in Africa, Elias Mpofu, PhD., DEd, CRC, Professor, Faculty of Health Sciences, University of Sydney, Cumberland Campus, East Street, PO Box 170 Lidcombe NSW 1825, Australia, email: elias.mpofu@sydney.edu.au. We encourage authors to submit manuscripts via e-mail, in MS Word, but we also require two hard copies of any e-mail submission. Before submitting a manuscript, authors should peruse and consult a recent issue of the *Journal of Psychology in Africa* for general layout and style. Manuscripts should conform to the publication guidelines of the latest edition of the American Psychological Association (APA) publication manual of instructions for authors.
**Manuscript format**

All pages must be numbered consecutively, including those containing the references, tables and figures. The typescript of a manuscript should be arranged as follows:

- **Title**: this should be brief, sufficiently informative for retrieval by automatic searching techniques and should contain important key-words (preferably <13 words).

- **Author(s) and Address(es) of author(s)**: The corresponding author must be indicated. The author's respective addresses where the work was done must be indicated. An e-mail address, telephone number and fax number for the corresponding author must be provided.

- **Abstract**: Articles and abstracts must be in English. Submission of abstracts translated to French, Portuguese and/or Spanish is encouraged. For data-based contributions, the abstract should be structured as follows: **Objective** - the primary purpose of the paper, **Method** - data source, participants, design, measures, data analysis, **Results** - key findings, implications, future directions and **Conclusions** - in relation to the research questions and theory development. For all other contributions (except editorials, book reviews, special announcements) the abstract must be a concise statement of the content of the paper. Abstracts must not exceed 150 words. The statement of the abstract should summarise the information presented in the paper but should not include references.

- **Text**: (1) Do not align text using spaces or tabs in references. Use one of the following: (a) use CTRL-T in Word 2007 to generate a hanging indent; or (b) MS Word allows author to define a style (e.g., reference) that will create the correct formatting. (2) Per APA guide-lines, only one space should follow any punctuation.
(3) Do not insert spaces at the beginning or end of paragraphs. (4) Do not use colour in text.

- **Tables:** Tables should be either included at the end of the manuscript or as a separate file. Indicate the correct placement by indicating the insertion point in brackets, e.g., <Inset Table 1 approximately here>. Tables should be provided as either tab-delimited text or as a MS Word table (One item/cell). Font for tables should be Helvetica text to maintain consistency.

- **Figures/Graphs/Photos:** Figures, graphs and photos should be provided in graphic format (either JPG or TIF) with a separate file for each figure, graph or photo. Indicate the correct placement by indicating the insertion point in brackets e.g., <Inset Figure 1 approximately here>. Provide the title for the item and any notes that should appear at bottom of item in the manuscript text. Items should be cropped to avoid the appearance of superfluous white space around items. Text on figures and graphs should be Helvetica to maintain consistency. Figures must not repeat data presented in the text or tables. Figures should be planned to appear to a maximum final width of either 80 or 175mm. (3.5 or 7.0”). Complicated symbols or patterns must be avoided. Graphs and histograms should preferably be two –dimensional and scale marks provided. All lines should be black but not too heavy or thick (including boxes). Colour only in photos or colour sensitive graphic illustrations. Extra charges will be levied for colour printing

**Referencing**

Referencing style should follow latest edition of the APA manual of instructions for authors.
• **References in text:** References in running text should be quoted as follows: (Louw & Mkize, 2012), or (Louw, 2011), or Louw (2000, 2004a, 2004b). All surnames should be cited the first time the reference occurs, e.g., Louw, Mkize, and Naidoo (2009) or (Louw, Mkize, & Naidoo, 2010). Subsequent citations should use et al., e.g. Louw et al. (2004) or (Louw et al., 2004). ‘Unpublished observations’ and ‘personal communications’ may be cited in the text, but not in the reference list. Manuscripts submitted but not yet published can be included as references followed by ‘in press’.

• **Reference list:** Full references should be given at the end of the article in alphabetical order, using double spacing. References to journals should include the author’s surnames and initials, the full title of the paper, the full name of the journal, the year of publication, the volume number, and inclusive page numbers. Titles of journals must not be abbreviated. References to books should include the authors’ surnames and **initials**, the year of publication, full title of the book, the place of publication, and the publisher’s name. References should be cited as per the examples below:

**Reference samples**

**Journal article**

**Book**

(edited book)

Chapter in a book

Magazine article

Newspaper article
(unsigned)

Permission from Mpumalanga Department of Health to conduct research

Dear Mrs Kolté,

RE: APPROVAL TO CONDUCT RESEARCH ON "THE EXPERIENCE OF EARLY MOTHERHOOD AMONGST SWAZI ADOLESCENT GIRLS" AT TONGA HOSPITAL WITHIN MPUMLANGA DEPARTMENT OF HEALTH AS PART OF REQUIREMENTS FOR MASTERS OF PSYCHOLOGY

1. The Provincial Research and Ethics Committee hereby grants approval for your research project on "the experience of early motherhood amongst Swazi Adolescent girls" which will be conducted at Tonga Hospital as part of your Masters Degree in Psychology at the North-West University.

2. It is noted that the purpose of your research, is as follows:

2.1 to conduct a literature study on the incidence and extent of adolescent pregnancies and motherhood, and critically evaluate previous research on these topics;

2.2 to describe and obtain an understanding of Swazi adolescent girls' experience of early motherhood through semi-structured one-on-one interviews; and

2.3 to provide guiding principles to District Hospitals' interdisciplinary team for an educational program on adolescent pregnancy awareness and prevention.
3. No issues of ethical consideration were identified.

4. The onus lies with the researcher to seek approval from the mentioned public health facility prior to conducting the research.

5. It should be noted however, that the department will be expecting a report on the findings, once the research project has been completed.

Yours faithfully,

[Signature]

ACTING HEAD OF DEPARTMENT

Mr. M. Ntisi

CONSENT TO PARTICIPATION OF STUDY

I am a Master's degree student in psychological research at the University of North-West and would like to invite you to take part in the study. Please read carefully through the information before signing the document.

Title

The experience of early motherhood amongst Swazi adolescent girls

Purpose of the study

The aim of this research is to gain information about the experiences of early motherhood amongst Swazi adolescent mothers between ages 12 to 18 years, in the Nkomazi district.

Description of procedures

An individual interview will be held with you in which will be asked about your experiences of being a mother.

The interview will not take longer than 60 minutes.

A tape recorder will be used to record the interviews.

The information on the tape recorder will be kept confidential and safe.

The interview will either take place at the hospital or at your home depending on your need.

The research findings will be made available to you should you request them.

Possible risks and discomforts

The study is non-therapeutic and there are no risks involved.

You might experience psychological/emotional discomfort due to personal questions that might be asked in the interview, but you will be free to answer only those questions that you feel comfortable with.
Benefits

There are no direct benefits to you, but the information obtained from this study can help Health Care providers with setting up a possible educational program for adolescents with regards to teenage pregnancy.

Incentives

Please note that there will be no financial incentive to participate in this study.

Voluntary participation

Your participation in this research is voluntary and you can withdraw from the study at any time.

Confidentiality

All information will be kept confidential and private.

You will not be identified in any document, including the interview transcript and the research report, by your surname, first name, or by any other information. You will be referred to in the documents under a code name only known to the researcher.

Some of your direct words will be quoted in the research report without mentioning your name but rather speaking about participant A/B.

No one will be informed about your participation in this research.

The tape recordings will only be viewed by the researcher and if necessary, by the supervisor, with your additional consent.

Rights of the participant

As previously discussed, you have the right to choose to participate in this study as well as the right to withdraw from the study at any given time. If you have any further questions regarding your participation in this research study, you may contact the researcher at any time (Alexa Kotze 072 239 2920).
I ________________ (name of participant) and ________________ (name of parent/guardian) have read and understood this document and agree to participate in the research.

Appendix E

Interview Guide

(Adapted from Weaver and Ussher (1997:55)

1. What made you decide to have children?
   
   Unqumeleni kakhulela?

2. What sort of things did you imagine about motherhood when you were pregnant?
   
   Wawucabangani usexhulelwwe ukuthi kuzubanjani ukuba ngumakhe?

3. How was your pregnancy and delivery?
   
   Bekunja ukhulelwwe nokazala kwakho?

4. What does it mean to you to be a mother?
   
   Uzwa kanjani kuba ngumakhe?

5. How has motherhood affected your life and your relationships with people?
   
   Ukuba ngumakhe kuthinte kanjani impilo yakho nobungane bakho nabanye bantu?

6. How has motherhood changed you as a person?
   
   Ushintshwe kanjani wena njengomunthu ngokuba ngumakhe?

7. What are the positive things about being a mother?
   
   Yiphi imiphumela emihle yokuba ngumakhe?
8. What are the challenges/difficulties about being a mother?

   Ziphi izinkinga ezilukhuni zokuba ngumakhe?

9. Why do you think women have children?

   Ucabangani ukuthi abesifazane bazalelani?

10. What advice would you give other teenagers who haven’t got babies yet?

    Uzoshe yini iseluleko sakho kulezinye izintombi ezingakakhulelwini?

11. What other questions do you think I should be asking mothers?

    Ucabangani ukuthi ngifanele ngibuze yiphi imibuzo kubomakhe?
Appendix F

Examples of unsuitable interviews

The following guidelines of Smith and Osborn (2007) were used to determine which of
the transcribed interviews would provide relevant information for further data analysis. The
measure of meaningfulness was judged objectively by the researcher considering the three
criteria: (a) appropriateness of the response to the question, (b) the linguistic sensibleness of
the response and (c) the length of the response.

Examples are given according to the criteria of interviews that could not be used due to
not abiding by the above mentioned criteria. The researcher’s question is indicated with an
“A” in the second column and the specific participant’s response is indicated with a “G” and
a number to identify the participants’ response.

(a) Appropriateness of the response to the question

<table>
<thead>
<tr>

### Appendix G

**Example of transcribed interview**
THE EXPERIENCE OF EARLY MOTHERHOOD AMONGST SWAZI ADOLESCENT GIRLS

Unwisely, thinking of what baby’s future needs will be.

155. 017 You can’t say you planned for him or her to buy its food for this month. Maybe sometimes he eats a lot, he eats less. Worry about provision for baby.

156. 017:17 "How much money do you think you will be able to save this year?"

157. 017 A. Mmm.

158. 017 A. Mmm.

159. 017 A. Mmm.

160. 017 A. Mmm.

161. 017 A. Mmm.

162. 017 A. Mmm.

163. 017 A. Mmm.

164. 017 A. Mmm.

165. 017 A. Mmm.

166. 017 A. Mmm.

167. 017 A. Mmm.

168. 017 A. Mmm.

169. 017 A. Mmm.

170. 017 A. Mmm.

171. 017 A. Mmm.

172. 017 A. Mmm.

173. 017 A. Mmm.

174. 017 A. Mmm.

175. 017 A. Mmm.

176. 017 A. Mmm.

177. 017 A. Mmm.

178. 017 A. Mmm.

179. 017 A. Mmm.

180. 017 A. Mmm.

181. 017 A. Mmm.

182. 017 A. Mmm.

183. 017 A. Mmm.

184. 017 A. Mmm.

185. 017 A. Mmm.

186. 017 A. Mmm.

187. 017 A. Mmm.

188. 017 A. Mmm.

189. 017 A. Mmm.

190. 017 A. Mmm.

191. 017 A. Mmm.

192. 017 A. Mmm.

193. 017 A. Mmm.

194. 017 A. Mmm.
Pregnancy was good — unaffected except for breast 137. G12. Ah, it was good, but I was too lazy.

138.

Laziness 139. A. Too lazy?

140.

141. G12. Ah, I was too lazy.

142.

143. A. Lazy or tired?

144.

Laziness and moody during pregnancy experience 145. G12. I was too lazy and stubborn.

146.

147. A. Is it?

148.

149. G12. Experience self as being stubborn during pregnancy.

150.

151. A. It?

152.

Feelings of anger 153. G12. Ja, at school they would say they would say something to me, whoa. I could easily get angry.

154.

155. A. (Laughter) And the pregnancy was it was it difficult for you to be carrying a child?

156.

158.

159. A. Okay.

160.

People discourage going to school when pregnant 161. G12. And people will tell me that I must stay at home not going to school and I say “Ah, I’m not feeling anything” and when I go when come back home I will say I am here now, I am tired, because it was so big and I didn’t mind that it was so big. Pretends to be unaffected by pregnancy.

162.

163. A. Okay.

164.

165. A. Ja, just go but I will feel tired afterwards.

166.

167. A. Okay, and while you were pregnant, your school, the relationships at the school, the teachers and your friends, how was that?

168.

Supportive teachers 169. G12. Ah, they were okay.

170.

171. A. Mmm?

172.

Supportive experience 173. G12. They were very supportive.

174.

175. A. They were?

176.

177. G12. Mmm.

178.

179. A. Okay. And you parents?

180.

181. A. My parents, or my mother was supportive but my father, they divorced.

182.

183. A. (Phone rings) Oopse, sorry. Let me just put it off. I thought it was off.

184.

185. G12. They divorced in 2003, so when my father found out that I was pregnant, oh she became angry, because she was maintain us. So he said my mother that he will stop maintaining us. Maintaining me for us exactly, because I’m supposed to be a child but now I’ve decided to be a parent’s wife, so I’ve got to be gone, where am I going to get the money?

186.

187. A. Stressed. Uhm, and uhm, did, ja, your delivery was it normal birth or was it caesarean?

188.

189. G12. It was normal.

190.

191. A. And how was that?

192.

Contraception: Feel pain during labour but didn’t feel pain?

193. G12. It, during the labour I didn’t hear anything, but after that feel the pain when I was at home the next day. Ja, that’s when I felt the pain, because in the labour I was in so much pain I didn’t care whatever they did.

194.

195. A. (Laughter)

196.

198.

199. A. Okay.

200.

Painful labour 201. G12. And I could someone “Ja it is painful”. You know (sighs).

202.

203. A. And was it long or was it short?

204.

205. G12. No it wasn’t, it was a short time because the labour started about eight at the night and by
one in the morning. I have already given birth.

209. A: Okay.
209. B.: mmm
210. A: And um, how long were you in hospital after that?
211. B.: For one day.
212. B.: One day.
213. A: Okay, Uhm, did anyone come and visit you?
214. A: Oh, they did but they, when they visit, the just took me home.
216. A: Okay, Uh, what does it mean to you to be a mother?
217. B.: Okay. What does it mean to you to be a mother?
218. A: Oh, it means a lot; it means a lot because I know that I've brought someone into this world. And I'm, I try my best to make sure that my baby gets everything that he wants.
219. A: He gets the best interest at heart.
220. B.: mmm
221. A: Feels adequate?
222. B.: Even though I don't have anything to offer him.
223. A: mmm
224. A: What is your definition, if you would say what is a mother according to you?
225. A: mmm. A mother is a shoulder to cry on. A person is a mother to be there for her baby. He must be there for her. So, that's what I'm trying to do.
226. A: mmm
227. A: And do you feel that you are accomplishing it?
228. A: She accompanies some of what she wants to do as mother.
229. B.: Some of it.
230. A: mmm
231. A: Sacrifice.
232. A: In order to give child what she needs, she sacrifices things that will enable her to be a better mother -- catch 22. For e.g., school.
233. B.: Some of it, because I have to sacrifice a lot.
234. A: What type of things do you sacrifice?
235. A: Like, my mother is working, so sometimes, or at most times she stays with the baby. So when she has to go away for an interview, I have to stay and go to school to look after that baby. And when my mother came home then she could stay with her. There's no one to stay with her.
236. A: Okay, what and how do you feel to be a mother?
237. B.: Sometimes it's good, sometimes it's bad. Because when she doesn't have food, he's small, he does not see anything, all he do is just when he's hungry he cries.
238. B.: Feels baby's pain.
239. A: And that pain, I'm the one who's feeling it and I am the one who has to make means to use that my baby now has that food that she will need, has everything that you'll need. Now here's winter, I have to make sure that he gets everything, jerseys and all that stuff.

she's just accepted that I have a baby.

418.

419. A. Okay. Uhm, emotionally, what difficulties do you have, what challenges?

420.

Mother sometimes look O: occupative

421. 422. Aw, somelime I could get verbally emotional. Just at the house you could find. I could find out that my baby is short of food and I have to tell my mother that my baby's food is going short and I don't have money to buy it. So she could be rude sometimes.

423.

424. A. mmm

425.

Fighting with mother She assumes I speak

426.

427. 428. She talks and talks and that hurts me because I know that the father of my child doesn't work so I can't just go and tell him that the baby is out of food. She'll ask me "where am I supposed to get money?"

429.

430. 431. That will hurt me too.

432.

433. A. mmm

434.

435. A. mmm

436.

437. A. Okay, and do you think you will still be able to go to university now that you've got a baby?

438.

439. 440. I will.

441. 442. Okay.

443. 444. 445. 446. It will. That I am sure of. I will go.

447.

448. A. Ambition to further education

449.

450. It will not stop you?

451.

452. A. No.

453.

454. A. And who will look after the baby then?

455.

Adoption to continue education

456. 457. I don't know, but the plan will open.

458.

459. A. Okay.

460.

461. A. Alright, uhm, why do you think women have children?

462.

463. 464. some for the wrong reasons, some by

</tr>
</tbody>
</table>
The experience of early motherhood amongst Swazi adolescent girls

581. A. In your situation, in the, your parents in law, are they involved?

584.

Parents in law not involved is baby they are deceased

585. GI. Oh, I must say that they are not, because the grandparents are not there, they are all dead. So there is just the young ones around. And they are having their own babies.

586. A. Okay, do you think they accept you?

587.

588. GI. They did, because those are the things that they have, they give us.

589. A. Okay.

590. GI. Ja.

591. A. Alright, anything else that you think I should know about being a mother and a teenage mother?

592.

595.

596.

Love my baby despite fact that she regrets having baby now

597. G1. When, on my side it’s ‘just love my baby’. Love for baby

598. A. You like your baby?

599.

600. A. Even when it’s difficult?

601.

602.

603. GI. Even, I have some difficult times, but I just put them aside. I have a amazing gift from God. That’s what they tell myself. That I won’t be against him, because it’s a gift from God. That’s why many people say that a child it’s a gift from God. So even if my side, I haven’t planned him but it is a gift from God even my side.

604.

605. A. Mmm

606.

607. GI. Ja.

608.

609. A. Okay, Uhm, one of the girls said a question I should ask them is why do teenagers do the things that they are not supposed to do? What do you think about that? If you say it wasn’t planned, why do...

610.

611. GI. Sometimes it’s due to influence of friends, like they pressure you.

612.

613. A. Is that what happened in your case?

614.

615. GI. No, it’s something that I have been doing, but I never thought that I could get pregnant. Ignorance about implication of sex

616.

617. GI. I have learned from my friends mistake but the other one I don’t know what’s wrong with her, because we try to talk to her just to come back to school, but she’s told us that she’s
looking after her baby, mean while she is
struggling with the baby's father and in the
circumstances everything is good because
the father is working, she gets everything she
wants, but she doesn't want to go back to
school. I don't know why.

But do you think, let us say if you had now
had a baby and initially you said it was a
mistake do you think umm, other girls look at
your life and then they say oh, I shouldn't
sleep around because I'm gonna get a baby or
I should use protection. DO you think girls
learn from it do they all need to make their
own mistake?

I, from what I've learnt that you can't tell a
person to do something that they don't want
to do. You can tell them that hey,
sleeping around is a bad thing because
you'll end up being pregnant and say
"because you got pregnant you think I will get
pregnant too. You see so, it's hard.

It's hard.

Teenagers are stubborn.

As, even if you could see that this person is
giving the wrong paths, you try to advise him or
her, but she will do, as you'll do mine. As.

So what if I come up with a teenage
pregnancy prevention program, do you think
they will, some of the girls will listen or you think
it will be useless?

Some of them will listen. Just not all of them,
because you know, someone's everyone here
what can I say, I do my own life, no one will
tell me what to do, but when you ended up in
such a bad, how mistake. you'll start
feeling around with people, needing help,
but at school we usually talk to many girls, As
because we are the most experienced one, so
we'll try all means to get those who don't have
babies to tell them that having a baby at
an early age is not good thing. But they listen,
very well, ja, they listen.

So you think it will work better if you actually
got girls that has got babies to speak to girls
that haven't got babies.

Yes, that haven't got babies. Yes. And the ones
who are having difficulties with their babies and
the one who are more advantaged. (phone ring)

What teachers talk to girls about pregnancy
prevention?

- mmh. Especially if you come to schools, so
that the teacher's, especially for the life
orientation teacher's they could gather the
girls around and talk to them.

- mm. mm.
- ja.

Okay. What do you think I am missing? That
must still know about? About being a
teenager and being a mother?

Oh, you have everything.

You think so?

Adolescent motherhood is good and bad

As. That is the key things that you need to
know, the hard, the negative and the positive
tings of being a teenage mother, because
most of us, it is when we are young.

Adolescent motherhood is good and bad.

My situation, I could say, having a baby it is
not an easy thing, because the things that we
usually experience, because we don't
experience the same things. Sometimes you
could see that, you could get that, a girl is
living with her parents and maybe that
is a girl used go and sleeping around, going to
parties, drinking, doing all that stuff. When
the baby is born, he will have the baby with
the grandparents to look after him, while
she's going drinking, doing the things that got
him into that certain trouble. ja.

Oh alright. Thank you very much for your
time. I appreciate it and your information I
think is very valuable.

### Appendix L

**Translation of quoted text used in article**

The following indicates the original verbatim interview before translation to English, in sequence as it appears in the article.

<table>
<thead>
<tr>
<th>Quotations taken from article</th>
<th>Initial verbatim interview</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;I thought some things were breaking (falling apart), really I didn’t want a child” (G10:77).</td>
<td>Ngacabanga loku loku phuka kwami ngatsi lokutshi cha vele umntfwana bengingamfuni</td>
</tr>
<tr>
<td>&quot;When I started changing shape, at two or four months, they didn’t talk to, to me” (G9:333).</td>
<td>Uma kungasi simo sami, 2 months or 4 months bangangi khulumisi.</td>
</tr>
<tr>
<td>&quot;You have to think for the child and it takes your money. Even if you get a little money and want to buy yourself something, you realise that you have to think of the child first and the money is only a little. If you find there is no food, it needs me to buy food” (G10:229).</td>
<td>Ngoba umntfwana uyamcabangela kani yena kutsi ungabamba imali lencane kufune ucabangele yena noma bofuna kutitsengela tiphahla takho mara uyocabanga kutsi kumele ngicala ngitsengele mntfwana before utitsengela wela ngitsi ngiyabuka imali yincane. Thole kutsi akunakudla funa ngitsenge kudla.</td>
</tr>
<tr>
<td>&quot;Other challenges of being a mother: It’s very annoying that I can’t care for my child. That I don’t have the money as a mother” (G9:467).</td>
<td>Lokunye lekumachalaltjisi kutsi ngibe ngumake neh. Kukhatsateke kakhulu kutsi ngingakhona mntfwanami kumsaphota neh. Kuthole kutsi anginamali ngingumake.</td>
</tr>
<tr>
<td>&quot;Ah, I don’t care about that. Now I am focused on learning. I learn even at night, I don’t go out. The sun goes down, but I’m inside looking at my books. If the child is sleeping, I am getting more clever learning my books. So that I can gain something at school, so I can finish grade 12” (G10:185).</td>
<td>Ah, angisabukiloyo nyalo ngititjela kutsi ngimele kufundza sikolo ngifundza amabhuku ami ebusuku angihambi ngihlale nihleli ilanga lingashona nginge endlini yami ngilale ngibuke emabhuku ami ngifundza.nangabe umntfwana wami alele bese ngiphaphame ngibuke emabhuku ami ngiyafundza. Kute nami ngitogaina esikoleni kute nami ngicedze grade 12.</td>
</tr>
<tr>
<td>&quot;Now, I realise I am a mother of a child. I don’t go to the guys anymore. I</td>
<td>Ah, nyalo vele ngitijelile. Ngingumake wemntfwana angisayeti tidvotakundzala takucala</td>
</tr>
</tbody>
</table>
- "used to go, thinking it's nice. Now, I don't want to, I feel like a mother of a child" (G10:201).

- "To be a mother is very difficult. To take care of a family and to raise a child you also show to other mothers what it is. And you have to be strong to be a mother and you have to fight the mother's fight. You see?" (G9:451).

- "I'm still fine, because I got used to it. I don't have problems now. Because I could never throw the child away" (G10:173).

- "In the end I accepted that I am a mother" (G9:321).

- "He goes out to have fun. It make my heart feel pain, I stay alone at home all the time" (G3:218).

- "To be a mother is very difficult in these times because things have now gone out of my reach" (G3:358).
